Reference Material (RM) Report

A Reference Material (RM) is a homogenous material with known and well-established analyte concentrations. RMs are processed in an identical manner to test samples, and are used to monitor and control the accuracy and precision of a test method for a typical sample matrix. RM results are expressed as percent recovery of the target analyte concentration. RM targets may be certified target concentrations provided by the RM supplier, or may be ALS long-term mean values (for empirical test methods).

Sub-Matrix:

					Reference Material (RM) Report				
					RM Target	Recovery (%)	Recovery Limits (%)

General Comments

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Refer to the ALS Quality Control Interpretive report (QCI) for applicable references and methodology summaries. Reference methods may incorporate modifications to improve performance.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Please refer to Quality Control Interpretive report (QCI) for information regarding Holding Time compliance.

Key : CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances

LOR: Limit of Reporting (detection limit).

Unit	*Description*
-	no units
%	percent
mg/kg	milligrams per kilogram
pH units	pH units

<: less than.

>: greater than.

Surrogate: An analyte that is similar in behavior to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED on SRN or QCI Report, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Qualifiers

Qualifier	*Description*
DLHM	*Detection Limit Adjusted: Sample has high moisture content.*
DLR	*Detection Limit Raised due to required dilution, limited sample amount, and/or high moisture content (soil samples).*

QUALITY CONTROL INTERPRETIVE REPORT

Work Order	: **YL2301043**	Page	: 1 of 20
Client	: **WSP Canada Inc.**	Laboratory	: ALS Environmental - Yellowknife
Contact	: E Irving	Account Manager	: Amber Springer
Address	: 840 Howe St, 10th Floor Vancouver BC Canada V6Z 2S9	Address	: 314 Old Airport Road, Unit 116 Yellowknife, Northwest Territories Canada X1A 3T3
Telephone	: ----	Telephone	: +1 867 873 5593
Project	: GOLD100-028	Date Samples Received	: 14-Aug-2023 10:00
PO	: 166372402/70000/03	Issue Date	: 21-Aug-2023 16:53
C-O-C number	: ----		
Sampler	: ----		
Site	: ----		
Quote number	: VA22-GOLD100-028		
No. of samples received	: 11		
No. of samples analysed	: 11		

This report is automatically generated by the ALS LIMS (Laboratory Information Management System) through evaluation of Quality Control (QC) results and other QA parameters associated with this submission, and is intended to facilitate rapid data validation by auditors or reviewers. The report highlights any exceptions and outliers to ALS Data Quality Objectives, provides holding time details and exceptions, summarizes QC sample frequencies, and lists applicable methodology references and summaries.

Key

Anonymous: Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number: Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO: Data Quality Objective.
LOR: Limit of Reporting (detection limit).
RPD: Relative Percent Difference.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Summary of Outliers

Outliers : Quality Control Samples

- No Method Blank value outliers occur.
- No Duplicate outliers occur.
- No Matrix Spike outliers occur.
- Laboratory Control Sample (LCS) outliers occur - please see following pages for full details.
- No Test sample Surrogate recovery outliers exist.

Outliers: Reference Material (RM) Samples

- No Reference Material (RM) Sample outliers occur.

Outliers : Analysis Holding Time Compliance (Breaches)

- No Analysis Holding Time Outliers exist.

Outliers : Frequency of Quality Control Samples

- No Quality Control Sample Frequency Outliers occur.

Outliers : Quality Control Samples

Duplicates, Method Blanks, Laboratory Control Samples and Matrix Spikes

Matrix: **Soil/Solid**

Analyte Group	Laboratory sample ID	Client/Ref Sample ID	Analyte	CAS Number	Method	Result	Limits	Comment
Laboratory Control Sample (LCS) Recoveries								
Metals	QC-MRG2-1091495 002	----	Boron	7440-42-8	E440	79.2 % MES	80.0-120%	Recovery less than lower control limit

Result Qualifiers

Qualifier	*Description*
MES	*Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).*

Analysis Holding Time Compliance

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times, which are selected to meet known provincial and /or federal requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by organizations such as CCME, US EPA, APHA Standard Methods, ASTM, or Environment Canada (where available). Dates and holding times reported below represent the first dates of extraction or analysis. If subsequent tests or dilutions exceeded holding times, qualifiers are added (refer to COA).

If samples are identified below as having been analyzed or extracted outside of recommended holding times, measurement uncertainties may be increased, and this should be taken into consideration when interpreting results.

Where actual sampling date is not provided on the chain of custody, the date of receipt with time at 00:00 is used for calculation purposes.

Where only the sample date without time is provided on the chain of custody, the sampling date at 00:00 is used for calculation purposes.

Matrix: **Soil/Solid**

Evaluation: × = Holding time exceedance ; ✓ = Within Holding Time

Legend & Qualifier Definitions

Rec. HT: ALS recommended hold time (see units).

Quality Control Parameter Frequency Compliance

The following report summarizes the frequency of laboratory QC samples analyzed within the analytical batches (QC lots) in which the submitted samples were processed. The actual frequency should be greater than or equal to the expected frequency.

Matrix: **Soil/Solid**

Evaluation: × = *QC frequency outside specification*; ✓ = *QC frequency within specification.*

Methodology References and Summaries

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Reference methods may incorporate modifications to improve performance (indicated by "mod").

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
pH by Meter (1:2 Soil:Water Extraction)	E108 ALS Environmental - Calgary	Soil/Solid	BC Lab Manual	pH is determined by potentiometric measurement with a pH electrode at ambient laboratory temperature (normally 20 ± 5°C), and is carried out in accordance with procedures described in the BC Lab Manual (prescriptive method). The procedure involves mixing the dried (at <60 ºC) and sieved (10mesh/2mm) sample with ultra pure water at a 1:2 ratio of sediment to water. The pH is then measured by a standard pH probe.
Moisture Content by Gravimetry	E144 ALS Environmental - Calgary	Soil/Solid	CCME PHC in Soil - Tier 1	Moisture is measured gravimetrically by drying the sample at 105°C. Moisture content is calculated as the weight loss (due to water) divided by the wet weight of the sample, expressed as a percentage.
Total Carbon by Combustion	E351 ALS Environmental - Saskatoon	Soil/Solid	CSSS (2008) 21.2 (mod)	Total Carbon is determined by the high temperature combustion method with measurement by an infrared detector.
Total Inorganic Carbon by Acetic Acid pH Standard Curve	E354 ALS Environmental - Saskatoon	Soil/Solid	CSSS (2008) 20.2	Total Inorganic Carbon is determined by acetic acid pH standard curve, where a known quantity of acetic acid is consumed by reaction with carbonates in the soil. The pH of the resulting solution is measured and compared against a standard curve relating pH to weight of carbonate.
Metals in Soil/Solid by CRC ICPMS	E440 ALS Environmental - Calgary	Soil/Solid	EPA 6020B (mod)	This method is intended to liberate metals that may be environmentally available. Samples are dried, then sieved through a 2 mm sieve, and digested with HNO3 and HCl. Dependent on sample matrix, some metals may be only partially recovered, including Al, Ba, Be, Cr, Sr, Ti, Tl, V, W, and Zr. Silicate minerals are not solubilized. Volatile forms of sulfur (including sulfide) may not be captured, as they may be lost during sampling, storage, or digestion. This method does not adequately recover elemental sulfur, and is unsuitable for assessment of elemental sulfur standards or guidelines. Analysis is by Collision/Reaction Cell ICPMS.
Mercury in Soil/Solid by CVAAS	E510 ALS Environmental - Calgary	Soil/Solid	EPA 200.2/1631 Appendix (mod)	Samples are dried, then sieved through a 2 mm sieve, and digested with HNO3 and HCl, followed by CVAAS analysis.

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
VH and F1 by Headspace GC-FID	E581.VH+F1 ALS Environmental - Calgary	Soil/Solid	BC MOE Lab Manual / CCME PHC in Soil - Tier 1 (mod)	Volatile Hydrocarbons (VH and F1) is analyzed by static headspace GC-FID. Samples are prepared in headspace vials and are heated and agitated on the headspace autosampler, causing VOCs to partition between the aqueous phase and the headspace in accordance with Henry's law. Analytical methods for CCME Petroleum Hydrocarbons (PHCs) are validated to comply fully with the Reference Method for the Canada-Wide Standard for PHC. Test results are expressed on a dry weight basis. Unless qualified, all required quality control criteria of the CCME PHC method have been met, including response factor and linearity requirements.
CCME PHCs - F2-F4 by GC-FID	E601.SG ALS Environmental - Calgary	Soil/Solid	CCME PHC in Soil - Tier 1	Sample extracts are subjected to in-situ silica gel treatment prior to analysis by GC-FID for CCME hydrocarbon fractions (F2-F4). Analytical methods for CCME Petroleum Hydrocarbons (PHCs) are validated to comply fully with the Reference Method for the Canada-Wide Standard for PHC. Test results are expressed on a dry weight basis. Unless qualified, all required quality control criteria of the CCME PHC method have been met, including response factor and linearity requirements.
BTEX by Headspace GC-MS	E611A ALS Environmental - Calgary	Soil/Solid	EPA 8260D (mod)	Volatile Organic Compounds (VOCs) are analyzed by static headspace GC-MS. Samples are prepared in headspace vials and are heated and agitated on the headspace autosampler, causing VOCs to partition between the aqueous phase and the headspace in accordance with Henry's law.
PAHs by Hex:Ace GC-MS (Low Level CCME)	E641A-L ALS Environmental - Calgary	Soil/Solid	EPA 8270E (mod)	Polycyclic Aromatic Hydrocarbons (PAHs) are extracted with hexane/acetone and analyzed by GC-MS. If reported, IACR (index of additive cancer risk, unitless) and B(a)P toxic potency equivalent (in soil concentration units) are calculated as per CCME PAH Soil Quality Guidelines fact sheet (2010) or ABT1.
Particle Size Analysis (Pipette) - MMER Classification	EC184E ALS Environmental - Saskatoon	Soil/Solid	Metal Mining Technical Guidance for Environmental Effects Monitoring (2012)	The particle size determination is performed by various methods to generate a Grain Size curve. The data from the curve is then used to produce particle size ranges based on the Metal Mining Effluent Regulations (MMER) classification system for Environmental Effects Monitoring.
Total Organic Carbon (Calculated) in soil	EC356 ALS Environmental - Saskatoon	Soil/Solid	CSSS (2008) 21.2	Total Organic Carbon (TOC) is calculated by the difference between total carbon (TC) and total inorganic carbon (TIC).
F1-BTEX	EC580 ALS Environmental - Calgary	Soil/Solid	CCME PHC in Soil - Tier 1	F1-BTEX is calculated as follows: F1-BTEX = F1 (C6-C10) minus benzene, toluene, ethylbenzene and xylenes (BTEX).

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Leach 1:2 Soil:Water for pH/EC	EP108 ALS Environmental - Calgary	Soil/Solid	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL	The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water.

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Digestion for Metals and Mercury	EP440 ALS Environmental - Calgary	Soil/Solid	EPA 200.2 (mod)	Samples are dried, then sieved through a 2 mm sieve, and digested with HNO_3 and HCl. This method is intended to liberate metals that may be environmentally available.
VOCs Methanol Extraction for Headspace Analysis	EP581 ALS Environmental - Calgary	Soil/Solid	EPA 5035A (mod)	VOCs in samples are extracted with methanol. Extracts are then prepared in headspace vials and are heated and agitated on the headspace autosampler, causing VOCs to partition between the aqueous phase and the headspace in accordance with Henry's law.
PHCs and PAHs Hexane-Acetone Tumbler Extraction	EP601 ALS Environmental - Calgary	Soil/Solid	CCME PHC in Soil - Tier 1 (mod)	Samples are subsampled and Petroleum Hydrocarbons (PHC) and PAHs are extracted with 1:1 hexane:acetone using a rotary extractor.
Dry and Grind in Soil/Solid <60°C	EPP442 ALS Environmental - Calgary	Soil/Solid	Soil Sampling and Methods of Analysis, Carter 2008	After removal of any coarse fragments and reservation of wet subsamples a portion of homogenized sample is set in a tray and dried at less than 60°C until dry. The sample is then particle size reduced with an automated crusher or mortar and pestle, typically to <2 mm. Further size reduction may be needed for particular tests.

General Comments

The ALS Quality Control (QC) report is optionally provided to ALS clients upon request. ALS test methods include comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against predetermined Data Quality Objectives (DQOs) to provide confidence in the accuracy of associated test results. This report contains detailed results for all QC results applicable to this sample submission. Please refer to the ALS Quality Control Interpretation report (QCI) for applicable method references and methodology summaries.

Key :

Anonymous = Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number = Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO = Data Quality Objective.
LOR = Limit of Reporting (detection limit).
RPD = Relative Percent Difference
# = Indicates a QC result that did not meet the ALS DQO.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Laboratory Duplicate (DUP) Report

A Laboratory Duplicate (DUP) is a randomly selected intralaboratory replicate sample. Laboratory Duplicates provide information regarding method precision and sample heterogeneity. ALS DQOs for Laboratory Duplicates are expressed as test-specific limits for Relative Percent Difference (RPD), or as an absolute difference limit of 2 times the LOR for low concentration duplicates within ~ 4-10 times the LOR (cut-off is test-specific).

Sub-Matrix: **Soil/Solid**

Method Blank (MB) Report

A Method Blank is an analyte-free matrix that undergoes sample processing identical to that carried out for test samples. Method Blank results are used to monitor and control for potential contamination from the laboratory environment and reagents. For most tests, the DQO for Method Blanks is for the result to be < LOR.

Laboratory Control Sample (LCS) Report

A Laboratory Control Sample (LCS) is an analyte-free matrix that has been fortified (spiked) with test analytes at known concentration and processed in an identical manner to test samples. LCS results are expressed as percent recovery, and are used to monitor and control test method accuracy and precision, independent of test sample matrix.

Sub-Matrix: **Soil/Solid**

Qualifiers

Qualifier	Description
MES	*Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).*

Matrix Spike (MS) Report

A Matrix Spike (MS) is a randomly selected intra-laboratory replicate sample that has been fortified (spiked) with test analytes at known concentration, and processed in an identical manner to test samples. Matrix Spikes provide information regarding analyte recovery and potential matrix effects. MS DQO exceedances due to sample matrix may sometimes be unavoidable; in such cases, test results for the associated sample (or similar samples) may be subject to bias. ND – Recovery not determined, background level >= 1x spike level.

Sub-Matrix: **Soil/Solid**

Reference Material (RM) Report

A Reference Material (RM) is a homogenous material with known and well-established analyte concentrations. RMs are processed in an identical manner to test samples, and are used to monitor and control the accuracy and precision of a test method for a typical sample matrix. RM results are expressed as percent recovery of the target analyte concentration. RM targets may be certified target concentrations provided by the RM supplier, or may be ALS long-term mean values (for empirical test methods).

Email 2:

Turnaround Time (TAT) Requested

☑ Routine [R] if received by 3pm M-F - no surcharges apply
☐ 4 day [P4] if received by 3pm M-F - 20% rush surcharge minimum
☐ 3 day [P3] if received by 3pm M-F - 25% rush surcharge minimum
☐ 2 day [P2] if received by 3pm M-F - 50% rush surcharge minimum
☐ 1 day [E] if received by 3pm M-F - 100% rush surcharge minimum
☐ Same day [E2] if received by 10am M-S - 200% rush surcharge.

Additional fees may apply to rush requests on weekends, statutory holidays and for non-routine tests.

Date and Time Required for all E&P TATs: dd-mmm-yy hh:mm am/pm

For all tests with rush TATs requested, please contact your AM to confirm availability.

Notes

[1] Canadian Council of Ministers of the Environment (CCME). 1999. Canadian Sediment Quality Guidelines for the Protection of Aquatic Life. In: Canadian Environmental Quality Guidleines, 1999, Canadian Council of Ministers of the Environment, Winnipeg, MB.

[2] Buchman, MF. 2008. NOAA Screening Quick Reference Tables, NOAA OR&R Report 08-1, Seattle, WA, Office of Response and Restoration Division, National Oceanic and Atmospheric Administration, 34 pages.

[a] CCME Guideline values substituted with the BC ENV Working Sediment Guideline in the absence of an applicable CCME Sediment Guideline

BC ENV = British Columbia Ministry of Environment; $CaCO_3$ = calcium carbonate; CCME = Canadian Council of Ministers of the Environment; ISQG = interim sediment quality guidelines; mg/kg = miligram per kilogram; mm= millimetre; NOAA = National Oceanic and Atmospheric Administration; PEL = probable effects levels; REL = Effect Range Low; SWQG = working sediment quality guidelines; T20 = Concentrations corresponding to 20% probability of observing toxicity; TEL= Threshold Effects Levels; T50 = Concentrations corresponding to 50% probably of observing toxicity; PEL = Probable Effect Levels; pH = scale of acidity; % - percentage; "-" = no value or no result available

Value	Greater than CCME ISQG guideline
Value	Greater than CCME ISQG and PEL guidelines
Value	Greater than NOAA sediment Benchmarks T_{20} guideline
Value	Greater than NOAA sediment Benchmarks TEL guideline
Value	Greater than NOAA sediment Benchmarks ERLguideline
Value	Greater than NOAA sediment Benchmarks T_{50} guideline
Value	Greater than NOAA sediment Benchmarks PEL guideline
Value	Greater than NOAA sediment Benchmarks ERM guideline
Value	Greater than NOAA sediment Benchmarks AET guideline

Notes

[1] Canadian Council of Ministers of the Environment (CCME). 1999. Canadian Sediment Quality Guidelines for the Protection of Aquatic Life. In: Canadian Environmental Quality Guidleines, 1999, Canadian Council of Ministers of the Environment, Winnipeg, MB.

[2] Buchman, MF. 2008. NOAA Screening Quick Reference Tables, NOAA OR&R Report 08-1, Seattle, WA, Office of Response and Restoration Division, National Oceanic and Atmospheric Administration, 34 pages.

[a] CCME Guideline values substituted with the BC ENV Working Sediment Guideline in the absence of an applicable CCME Sediment Guideline

BC ENV = British Columbia Ministry of Environment; $CaCO_3$ = calcium carbonate; CCME = Canadian Council of Ministers of the Environment; ISQG = interim sediment quality guidelines; mg/kg = milligram per kilogram; mm= millimetre; NOAA = National Oceanic and Atmospheric Administration; PEL = probable effects levels; REL = Effect Range Low; SWQG = working sediment quality guidelines; T20 = Concentrations corresponding to 20% probability of observing toxicity; TEL= Threshold Effects Levels; T50 = Concentrations corresponding to 50% probably of observing toxicity; PEL = Probable Effect Levels; pH = scale of acidity; % - percentage; "-" = no value or no result available

Value	Greater than CCME ISQG guideline
Value	Greater than CCME ISQG and PEL guidelines
Value	Greater than NOAA sediment Benchmarks T_{20} guideline
Value	Greater than NOAA sediment Benchmarks TEL guideline
Value	Greater than NOAA sediment Benchmarks ERLguideline
Value	Greater than NOAA sediment Benchmarks T_{50} guideline
Value	Greater than NOAA sediment Benchmarks PEL guideline
Value	Greater than NOAA sediment Benchmarks ERM guideline
Value	Greater than NOAA sediment Benchmarks AET guideline

Notes

[1] Canadian Council of Ministers of the Environment (CCME). 1999. Canadian Sediment Quality Guidelines for the Protection of Aquatic Life. In: Canadian Environmental Quality Guidleines, 1999, Canadian Council of Ministers of the Environment, Winnipeg, MB.

[2] Buchman, MF. 2008. NOAA Screening Quick Reference Tables, NOAA OR&R Report 08-1, Seattle, WA, Office of Response and Restoration Division, National Oceanic and Atmospheric Administration, 34 pages.

[a] CCME Guideline values substituted with the BC ENV Working Sediment Guideline in the absence of an applicable CCME Sediment Guideline

BC ENV = British Columbia Ministry of Environment; $CaCO_3$ = calcium carbonate; CCME = Canadian Council of Ministers of the Environment; ISQG = interim sediment quality guidelines; mg/kg = milligram per kilogram; mm= millimetre; NOAA = National Oceanic and Atmospheric Administration; PEL = probable effects levels; REL = Effect Range Low; SWQG = working sediment quality guidelines; T20 = Concentrations corresponding to 20% probability of observing toxicity; TEL= Threshold Effects Levels; T50 = Concentrations corresponding to 50% probably of observing toxicity; PEL = Probable Effect Levels; pH = scale of acidity; % - percentage; "-" = no value or no result available

Value	Greater than CCME ISQG guideline
Value	Greater than CCME ISQG and PEL guidelines
Value	Greater than NOAA sediment Benchmarks T_{20} guideline
Value	Greater than NOAA sediment Benchmarks TEL guideline
Value	Greater than NOAA sediment Benchmarks ERLguideline
Value	Greater than NOAA sediment Benchmarks T_{50} guideline
Value	Greater than NOAA sediment Benchmarks PEL guideline
Value	Greater than NOAA sediment Benchmarks ERM guideline
Value	Greater than NOAA sediment Benchmarks AET guideline

Notes

[1] Canadian Council of Ministers of the Environment (CCME). 1999. Canadian Sediment Quality Guidelines for the Protection of Aquatic Life. In: Canadian Environmental Quality Guidelines, 1999, Canadian Council of Ministers of the Environment, Winnipeg, MB.

[2] Buchman, MF. 2008. NOAA Screening Quick Reference Tables, NOAA OR&R Report 08-1, Seattle, WA, Office of Response and Restoration Division, National Oceanic and Atmospheric Administration, 34 pages.

[a] CCME Guideline values substituted with the BC ENV Working Sediment Guideline in the absence of an applicable CCME Sediment Guideline

BC ENV = British Columbia Ministry of Environment; $CaCO_3$ = calcium carbonate; CCME = Canadian Council of Ministers of the Environment; ISQG = interim sediment quality guidelines; mg/kg = miligram per kilogram; mm= millimetre; NOAA = National Oceanic and Atmospheric Administration; PEL = probable effects levels; REL = Effect Range Low; SWQG = working sediment quality guidelines; T20 = Concentrations corresponding to 20% probability of observing toxicity; TEL= Threshold Effects Levels; T50 = Concentrations corresponding to 50% probably of observing toxicity; PEL = Probable Effect Levels; pH = scale of acidity; % - percentage; "-" = no value or no result available

Value	Greater than CCME ISQG guideline
Value	Greater than CCME ISQG and PEL guidelines
Value	Greater than NOAA sediment Benchmarks T_{20} guideline
Value	Greater than NOAA sediment Benchmarks TEL guideline
Value	Greater than NOAA sediment Benchmarks ERLguideline
Value	Greater than NOAA sediment Benchmarks T_{50} guideline
Value	Greater than NOAA sediment Benchmarks PEL guideline
Value	Greater than NOAA sediment Benchmarks ERM guideline
Value	Greater than NOAA sediment Benchmarks AET guideline

Notes

[1] Canadian Council of Ministers of the Environment (CCME). 1999. Canadian Sediment Quality Guidelines for the Protection of Aquatic Life. In: Canadian Environmental Quality Guidleines, 1999, Canadian Council of Ministers of the Environment, Winnipeg, MB.

[(a)CCME] Guideline values substituted with the BC ENV Working Sediment Guideline in the absence of an applicable CCME Sediment Guideline

BC ENV = British Columbia Ministry of Environment; CCME = Canadian Council of Miniters of the Environment; ISQG = interim sediment quality guidelines; mg/kg = miligram per kilogram; NOAA = National Oceanic and Atmospheric Administration; PEL = probable effects levels; REL = Effect Range Low; SWQG = working sediment quality guidelines; T20 = Concentrations corresponding to 20% probability of observing toxicity; TEL= Threshold Effects Levels; T50 = Concentrations corresponding to 50% probably of observing toxicity; PEL = Probable Effect Levels; pH = scale of acidity; % - percentage; "-" = no value or no result available

Value	Greater than CCME ISQG guideline
Value	Greater than CCME ISQG and PEL guidelines
Value	Greater than NOAA sediment Benchmarks T_{20} guideline
Value	Greater than NOAA sediment Benchmarks TEL guideline
Value	Greater than NOAA sediment Benchmarks ERLguideline
Value	Greater than NOAA sediment Benchmarks T_{50} guideline
Value	Greater than NOAA sediment Benchmarks PEL guideline
Value	Greater than NOAA sediment Benchmarks ERM guideline
Value	Greater than NOAA sediment Benchmarks AET guideline

APPENDIX 3G

Power Analysis

POWER ANALYSIS - METHODS

A Type I error is concluding there is a significant effect when none exists (i.e., a false positive). Alpha (α) is the probability of committing a Type I error. A Type II error is the probability of concluding there is no significant effect when there is a real effect of some specified magnitude (i.e., a false negative). Beta (β) is the probability of committing a Type II error. The power of a statistical test (1 - β) is the probability of detecting a real effect. In this analysis, the Type I error-rate (α), also referred to as the significance level, was set to 0.05. The desired minimum statistical power was 80%, which corresponds to a type II error-rate of 0.2. Power analyses were conducted to assess the power of statistical tests under multiple effect sizes. For each model, a set of effect sizes was created, based on preliminary power analyses, so that power >80% was achieved at the largest absolute values of effect sizes, but also so that power is assessed at a range of effect sizes. Both negative and positive effect sizes were used, to assess the power of detecting either a reduction or an increase in values of the response variables. Since the analysis focused on assessment of changes to statistical power at different effect sizes, the power analysis used the observed samples sizes from the collected data.

Data Simulation following Effect Size Application

The power to detect statistically significant effects was estimated using residual bootstrapping in R v. 4.3.2 (R 2023), following the approach of Fox and Weisberg (2018). The general approach was to simulate data based on the model selected for interpretation, the observed sample size, and the residuals, and re-run the models that were used for the original analysis using the simulated data. The data simulation and analysis were repeated 5,000 times, and the proportion of repetitions where the *P*-values of interest were significant ($P<0.05$) was interpreted as the statistical power of the test.

To produce simulated data, the original model was used to predict values of the response variable. The predicted values were then adjusted according to the effect size, depending on the analysis (see below for details). The simulated data were then analyzed using the same model structure as the original analysis. Effect sizes and statistical tests were applied differently to different models, as detailed below.

Effect Sizes

In this power analysis, the question of interest was the models' power to detect between-year differences at various distances within transect, as well as the power to detect a significant trend over time along each transect.

To assess the power to detect spatial trends, the effect size was applied linearly, where the first sampling station in each transect had the full effect size, whereas the last sampling station along the transect had an effect size of zero. This simulated the expected distribution, where disturbance was highest in close proximity to the ore dock. The effect sizes were calculated relative to the observed values at maximum distance along each transect, since it was assumed that at the end of each transect, disturbance was minimal. The effect size was only applied to 2023 data, whereas all data collected previously only had an effect size of zero. This allowed assessing what effect size, relative to the values in low-disturbance portion of each transect, the model would be able to identify. The effect size was applied up to a distance of 1,000 m from transect origin, such that at the beginning of the transect, the effect size was applied fully, decreasing linearly with distance until reaching 0% effect size at a distance of 1,000 m. This distance was selected as a previous assessment of ship wake and propeller wash indicated that sediment scouring and deposition would be limited to less than 1,000 m from the dock (Golder 2018). An example

of the effect size application to the Post-2018 Dataset (i.e., 2019, 2020, and 2023) for fines content is provided in Figure 3G-1.

To assess the power to detect between-year differences, the effect size was applied differently than for the effect of distance. Specifically, the effect size was also applied linearly relative to distance from transect origin, and it was also only applied to 2023 data. However, the effect size was calculated relative to the values observed in the previous sampling year (i.e., 2020). This allowed assessing what effect size, relative to the previous sampling year, the model would be able to identify.

The simulated data based on effect sizes applied to values of the response variable from 2023 were combined with simulated data from previous years (with an effect size of zero). This combined dataset was analyzed using the models from the original analysis in the main report.

To estimate the power to detect a spatial effect, the significance of the spatial trend in 2023 was assessed at 500 m and 700 m from transect origin (for Northeast Transect) and at 250 m and 500 m from transect origin (for all other transects) using the package emmeans (Lenth 2019), and the minimum *P*-values for the trend across both distances were retained. The use of two distances per transect allowed the estimation of power to detect at least one significant spatial trend per transect. The proportion of repetitions with *P*-values less than 0.05 was interpreted as the statistical power to detect a spatial effect.

Power to detect a temporal effect differed between analyses that used year as a continuous variable and those that used year as a categorical variable. For analyses that used year as a continuous variable (fines content and iron concentrations from the Entire Dataset [2014-2020, and 2023]), the significance of the trend at a value of 2022.5 (i.e., half a year prior to the 2023 sampling) was assessed at 500 m from transect origin using the package emmeans (Lenth 2019), and the *P*-values for the trend at each distance were retained. This time was selected to represent the period between the previous and current sampling years. The proportion of repetitions with *P*-values less than 0.05 was interpreted as the statistical power to detect a temporal effect. For analyses that used year as a categorical variable (fines content and iron concentrations from the Post-2018 Dataset), the significance of the difference between 2023 and 2022 was assessed at 500 m from transect origin, and the *P*-value for the comparison was retained. For each effect size, the proportion of repetitions with *P*-values less than 0.05 at each transect was interpreted as the statistical power to detect a year effect. This analysis assessed how much higher or lower the 2023 values would have to be to detect a significant difference relative to the previous sampling year.

Power Analysis – Reporting of Results

Power curves were produced, showing statistical power as a function of effect size in percentages. Horizontal lines were added to visualize statistical power values of 0.8 (hereafter sufficient power) and 0.9 (hereafter high power), and a vertical line was added to visualize the magnitude of difference (or the slope value, for continuous predictor variables) that was observed in the original analysis.

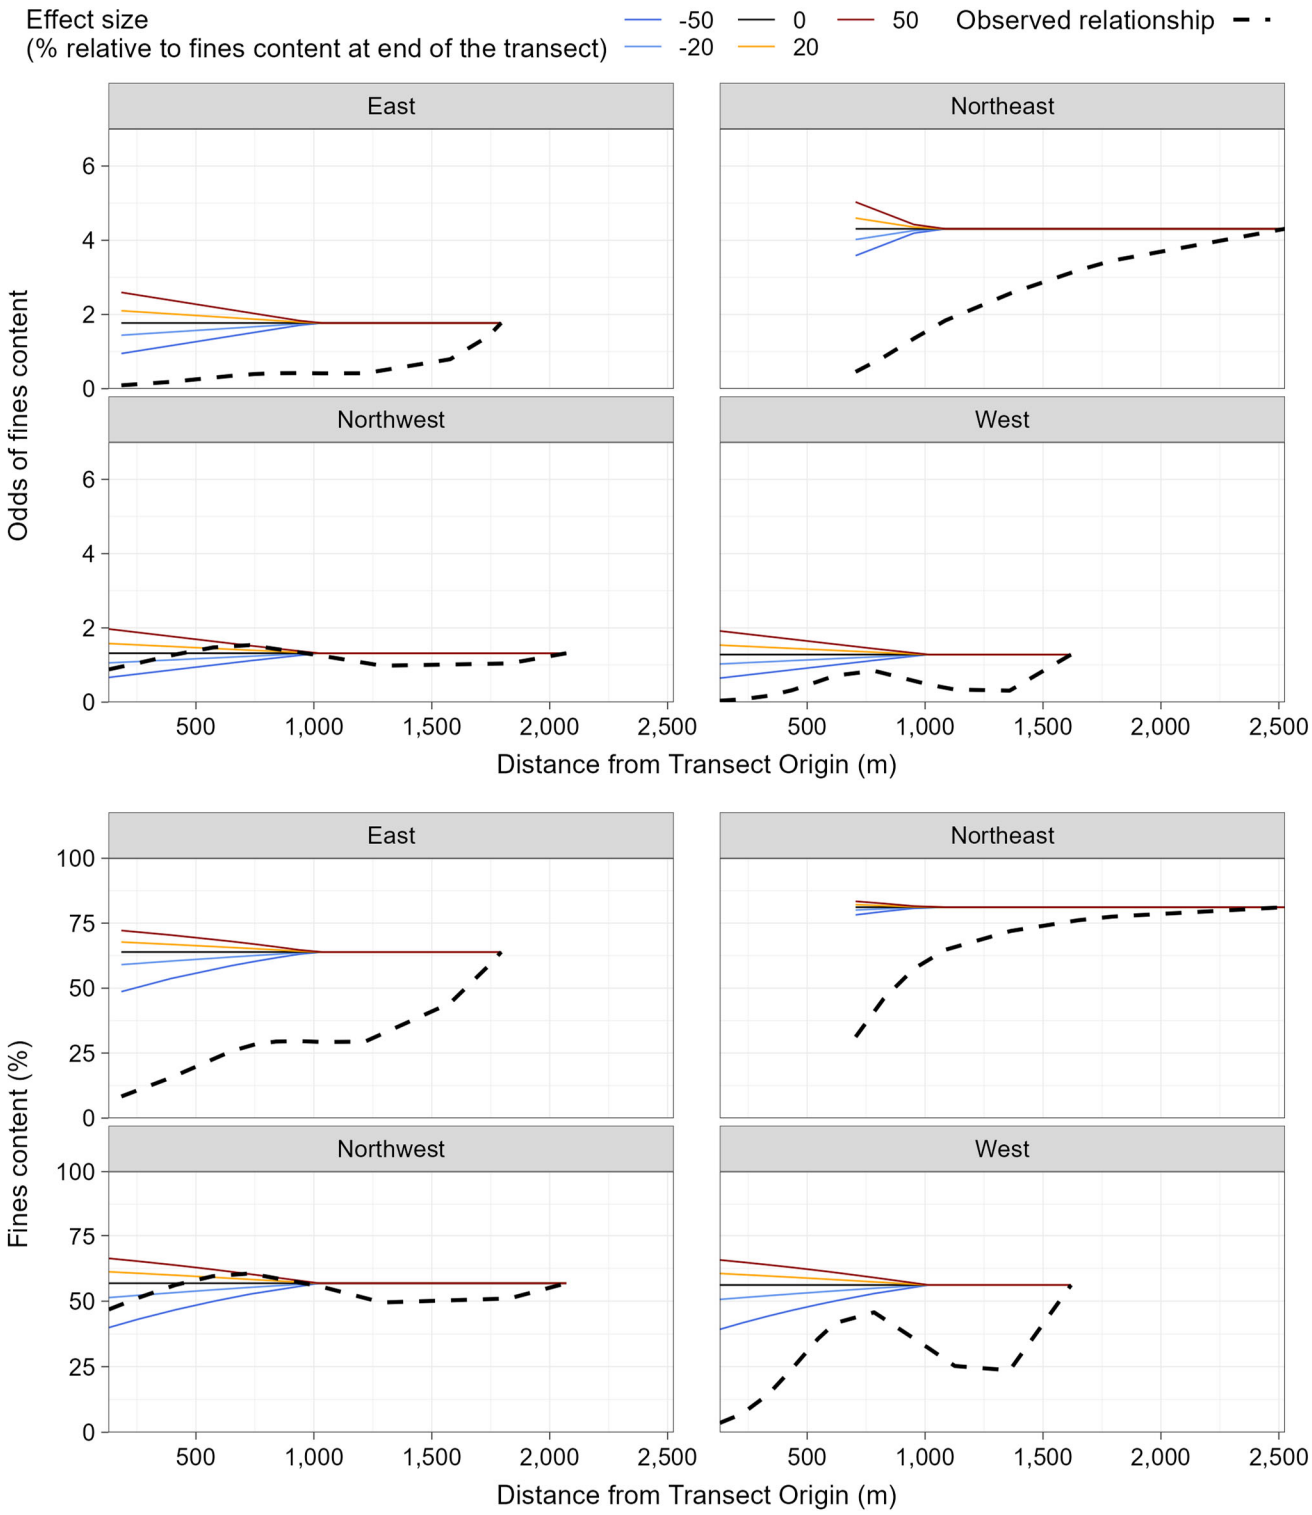

Figure 3G-1: Application of effect sizes to examine effect of distance in fines (2019-2023 percent fines model), illustrating how effect sizes applied on the odds scale (top) are affected by the bounding of fines content by 0% and 100% once effect sizes are expressed on the percent scale (bottom).

POWER ANALYSIS – RESULTS

Sediment Quality – Percent Fines in Post-2018 Dataset

The power analysis indicated that the analysis of percent fines data collected in the Post-2018 Dataset had sufficient power (>0.8) to detect a spatial effect of scouring (i.e., decrease in fines content) at effect sizes of -65%, -70%, -70%, and -65% for the East, Northeast, Northwest, and West transects, respectively (Figure 3G-2). Most observed effect sizes in 2023 ranged from -94% (East Transect) to -90% (Northeast Transect), with the exception of the Northwest Transect, where observed effect size was -21%. Since most observed effect sizes were larger than the effect sizes required for sufficient power, the model had high power (>0.9) to detect the observed effect sizes for all transects except the Northwest Transect. This is consistent with the finding of a significant two-way interaction between distance and transect in the original analysis of percent fines (P<0.001; Section 3.4.5.1 in the 2023 MEEMP main report [WSP 2024]). The model had low power to detect increases in fines in the proximity to transect origins. Since all transects had lower fines content close to transect origins when compared to the end of the transects (Section 3.4.5.1 in the 2023 MEEMP main report [WSP 2024]), the statistical power to detect scouring, rather than deposition, was considered to be more relevant.

For the temporal effects, the model had sufficient power (>0.8) to detect a temporal effect of scouring at effect sizes ranging between -85% (East Transect) and -55% (Northeast Transect) and an increase in fines content ranging between 100% (Northwest and West transects) and 150% (East, Northeast transects; Figure 3G-2). That is, the model had higher power to detect a decrease in fines content between 2020 and 2023. Power was higher for the analysis to detect an increase in fines over time compared to a spatial increase in fines. Observed effect sizes ranged from -36% (West Transect) to +27% (Northwest Transect). Statistical power to detect observed effect sizes was low, which is consistent with lack of significance of all year effect terms in the original analysis of percent fines (P>0.1 for all; Section 3.4.5.1 in the 2023 MEEMP main report [WSP 2024]).

Overall, power to detect observed spatial trends was high, whereas power to detect observed temporal trends was low, which is consistent with the absolute values of observed temporal effects being smaller than those of the spatial effects.

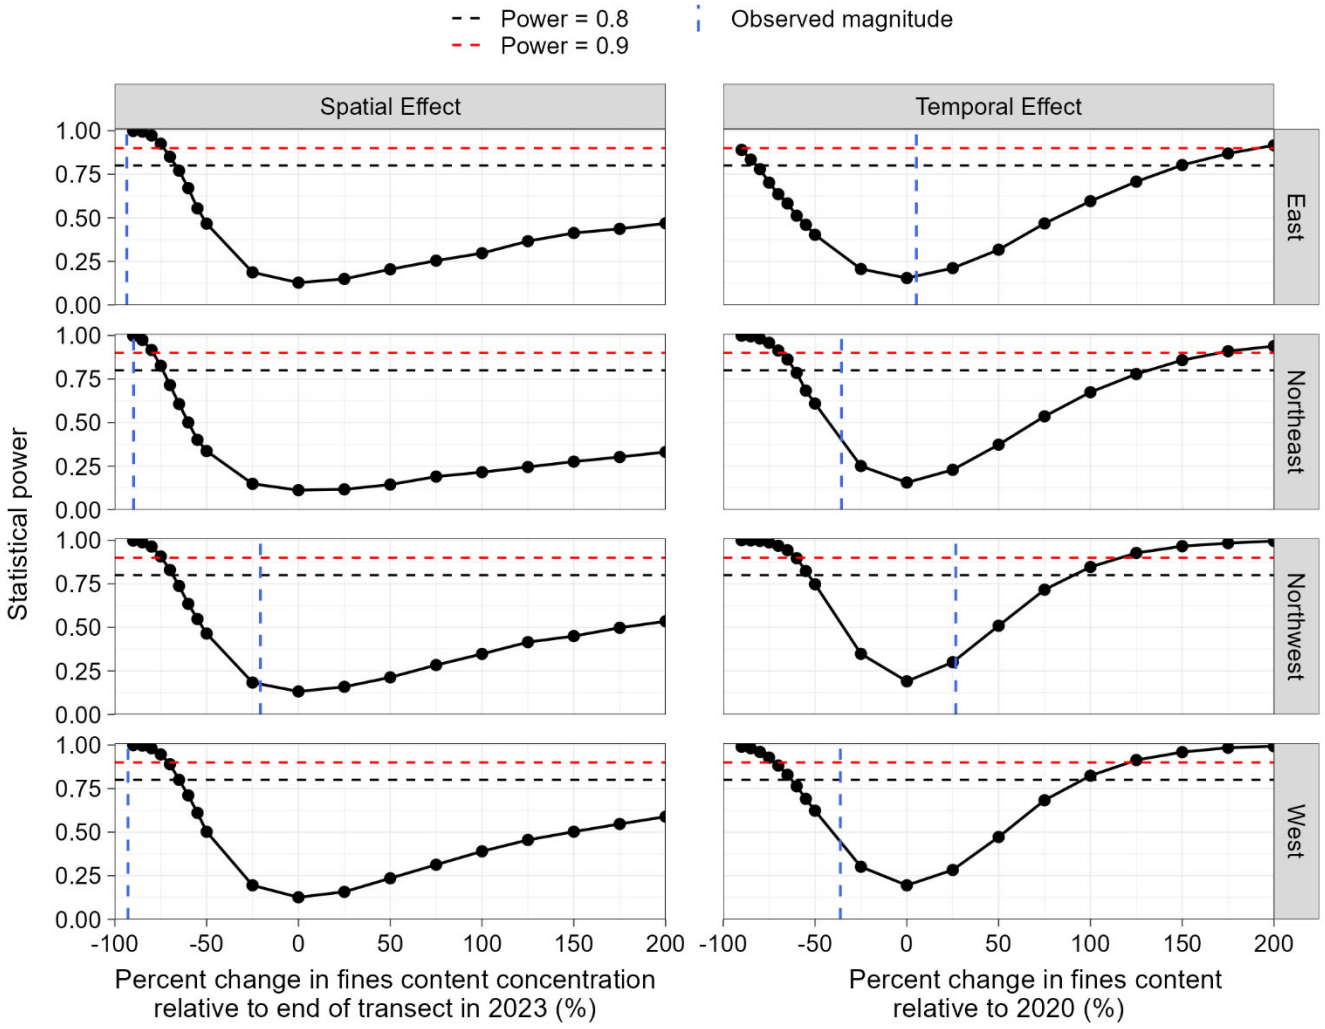

Figure 3G-2: Statistical power of the 2019-2023 percent fines model to detect a significant spatial trend (left) and a significant difference between 2020 and 2023 (right). Both spatial and temporal effects were tested at 500 m and 700 m from transect origin (for northwest transect) and 250 m and 500 m from transect origin (for all other transects).

Sediment Quality – Percent Fines in 2014-2023

The power analysis indicated that the analysis of percent fines in the Entire Dataset had sufficient power (>0.8) to detect spatial effect of scouring (i.e., decrease in fines content) at effect sizes of -70%, -65%, and -70% for the East, West, and North transects, respectively (Figure 3G-3). Observed effect sizes in 2023 were -94%, -93%, and -20% for the East, West, and North transects, respectively. The model had high power (>0.9) to detect the observed effect size for the East and West transects, but low power (<0.5) to detect the effect size observed at the North Transect. This is consistent with the finding of a significant increasing trend near the transect origin for East and West transects, but not for the North transect (Section 3.4.5.1 in the 2023 MEEMP main report [WSP 2024]). The model had low power to detect increases in fines in the proximity to transect origins, especially for East and North transects. Since transects had lower fines content close to transect origins when compared to the end of the transects for most of the sampling years (Section 3.4.5.1 in the 2023 MEEMP main report [WSP 2024]), the statistical power to detect scouring, rather than deposition, was considered to be more relevant.

For the temporal effects, the model had sufficient power (>0.8) to detect a 70% and 80% decrease in fines content ranging for the East and North transects, respectively, but not for any of the examined negative effect sizes for the West Transect (Figure 3G-3). The lack of power to detect a decrease in fines between 2020 and 2023 close to the West Transect origin was due to the already low values of fines in 2020 (Section 3.4.5.1 in the 2023 MEEMP main report [WSP 2024]). The model had sufficient power (>0.8) to detect increases in fines content that were 500%, 125%, and 175% higher in 2023 compared to 2020 for the East, West, and North transects, respectively. That is, the model generally had higher power to detect a decrease in fines content between 2020 and 2023 but had higher power to detect an increase in fines over time than a spatial increase in fines. Observed effect sizes were -25%, -27%, and +39% for the West, East, and North transects, respectively. Statistical power to detect observed effect sizes was low, which is consistent with lack of significant temporal trends between 2020 and 2023 at 500 m from transect origin for West and North transects (Section 3.4.5.1 in the 2023 MEEMP main report [WSP 2024]).

Overall, power to detect observed spatial trends was high, whereas power to detect observed temporal trends was low, which is consistent with the absolute values of observed temporal effects being smaller than those of the spatial effects.

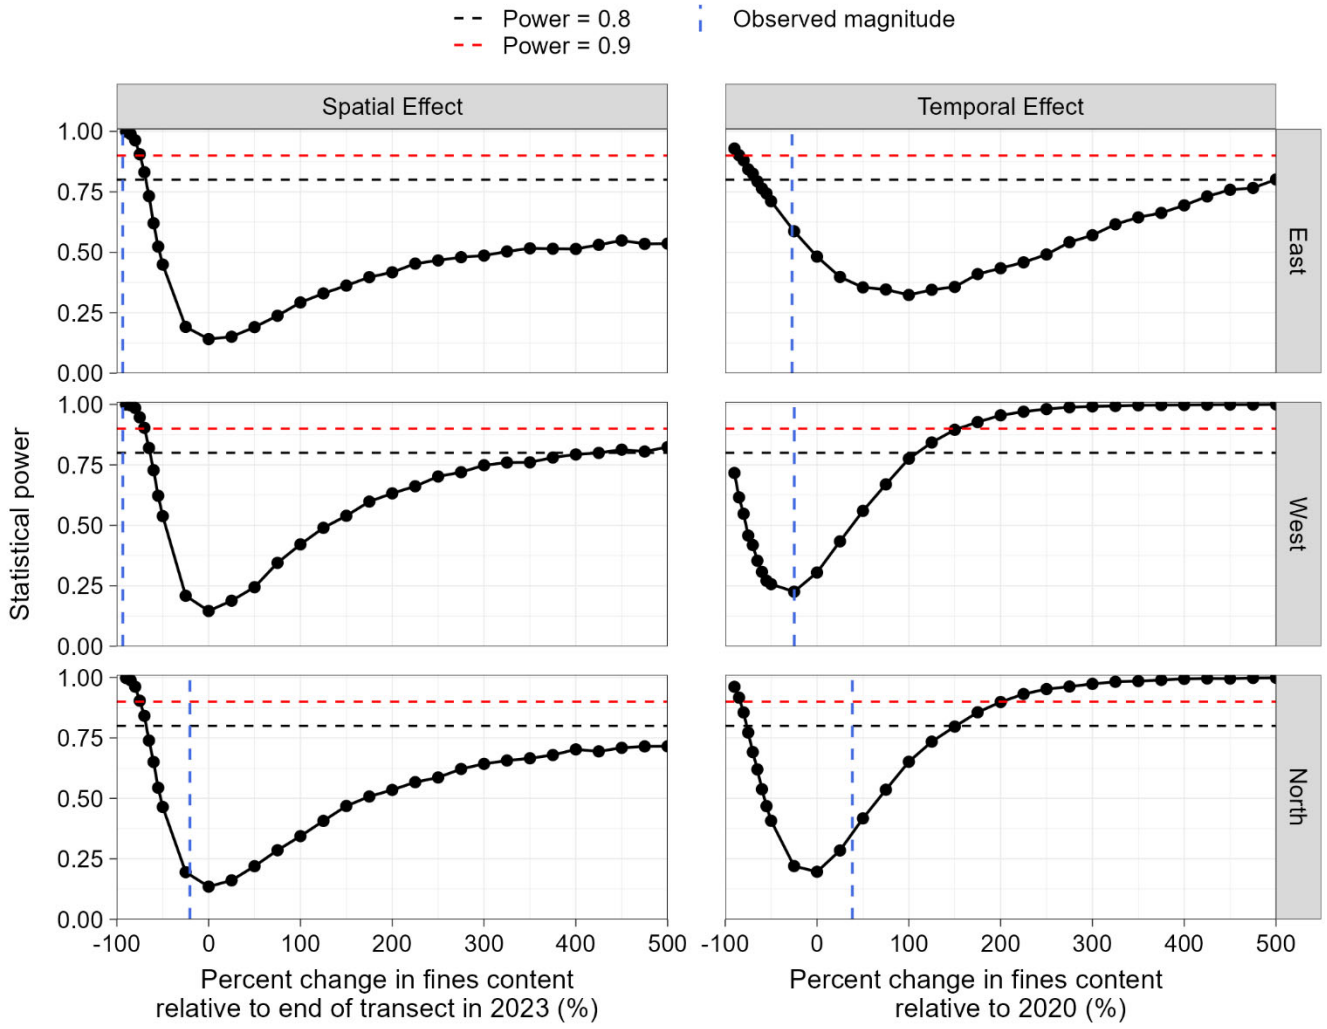

Figure 3G-3: Statistical power of the 2014-2023 percent fines model to detect a significant spatial trend (left) and a significant temporal trend in 2023 (right). Both spatial and temporal effects were tested at 250 m and 500 m from transect origin.

Sediment Quality – Iron Concentrations in Post-2018 Dataset

The power analysis indicated that the analysis of iron concentration data collected in the Post-2018 Dataset had sufficient power (>0.8) to detect spatial decreases in fines-adjusted iron concentrations at effect sizes of -35% for both Northwest and Northeast transects, but not at any of the negative effect sizes for East and West transects (Figure 3G-4). The low power to detect decreasing iron concentrations at the East and West transects was due to the low fines content in proximity to the transect origins. Since low fines would be associated with low iron concentrations, the simulated decreases in iron had little effect, resulting in low statistical power. The model had sufficient power to detect increases in iron concentrations in the proximity to transect origins at effect sizes of +120%, +30%, +35%, and +140% for the East, Northeast, Northwest, and West transects, respectively (Figure 3G-4). Observed effect sizes in 2023 were +38%, +5%, +6%, and -31% for the East, Northwest, Northeast, and West transects, respectively. The model had sufficient power to detect the observed effect size for the Northeast Transects, but low power to detect the effect size observed at the other transects. This is consistent with the finding of a significant increasing trend near the transect origin for Northeast Transect in 2023 but not for the other transects transect (Section 3.4.5.1 in the 2023 MEEMP main report [WSP 2024]).

For the temporal effects, the model had sufficient power (>0.8) to detect a 35%, 35%, 15%, and 25% decreases or increases in iron concentrations for the East, Northeast, Northwest, and West transects, respectively (Figure 3G-4). That is, the model had higher power to detect a change in iron concentrations over time than a spatial increase in concentrations. Observed effect sizes were +11%, +20%, +7%, and +3% for the East, Northeast, Northwest, and West transects, respectively. Statistical power to detect observed effect sizes was low (<0.5). While the multiple comparisons between years in the original analysis found a significant difference between 2020 and 2023 for the Northwest Transect (Section 3.4.5.1 in the 2023 MEEMP main report [WSP 2024]), it is important to note that this comparison was calculated across all distances from transect origin, while the power analysis estimates were calculated for specific distances along the transect.

Overall, power to detect spatial effects was higher for the Northeast and Northwest transects than for the East and West transects, while power to detect temporal effects was highest for the Northwest and West transects. Power to detect observed spatial and temporal trends was low for seven of the eight effects, however only three of the either observed effects had an absolute value larger than 15% (spatial effects for the East and Northeast transects, and temporal effect for the Northeast Transect).

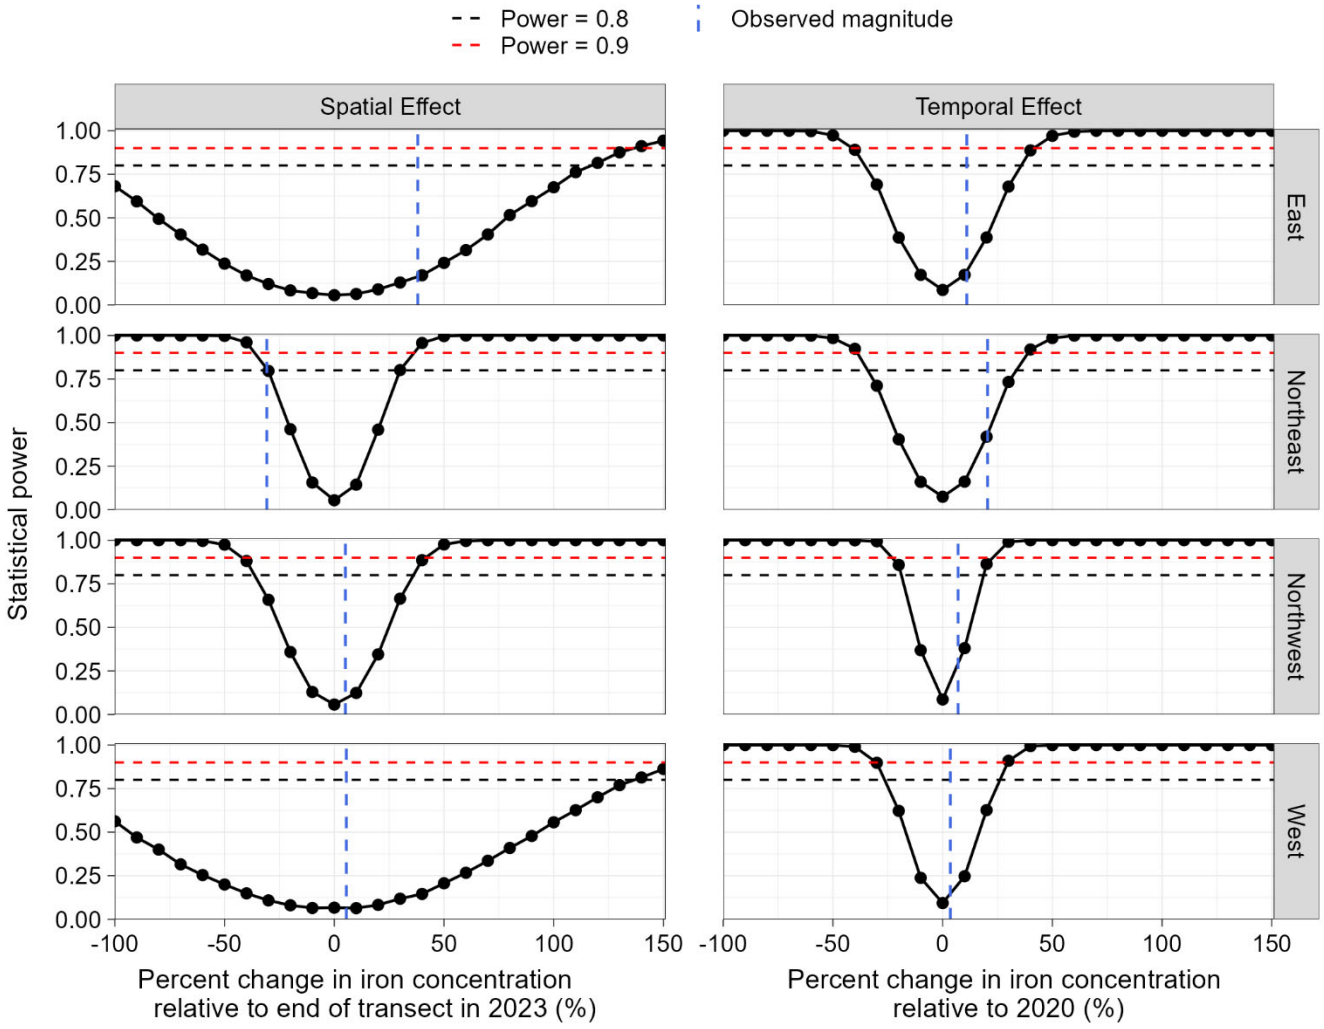

Figure 3G-4: Statistical power of the 2019-2023 iron concentration model to detect a significant spatial trend (left) and a significant difference between 2020 and 2023 (right). Both spatial and temporal effects were tested at 500 m and 700 m from transect origin (for northwest transect) and 250 m and 500 m from transect origin (for all other transects).

Sediment Quality – Iron Concentrations in 2014-2023

The power analysis indicated that the analysis of iron concentration data collected in 2014-2023 had sufficient power (>0.8) to detect spatial decreases in fines-adjusted iron concentrations only at effect size of -35% for the North Transect, and not for any of the negative effects at the remaining two transects (Figure 3G-5). The model had sufficient power to detect increases in iron concentrations in the proximity to transect origins at effect sizes of +110%, +110%, and +35% for the East, West, and North transects, respectively. Observed effect sizes in 2023 were +37%, +6%, and +3% for the East, West, and North transects, respectively. The model had low power (<0.5) to detect the observed effect sizes at all three transects.

For the temporal effects, the model had sufficient power (>0.8) to detect a 65%, 40%, and 25% decrease in fines-adjusted iron concentrations for the East, West, and North transects, respectively, as well as a 50%, 35%, and 30% increases for the East, West, and North transects, respectively (Figure 3G-5). Observed effect sizes were +12%, +16%, and +8% for the East, West, and North transects, respectively. Statistical power to detect observed effect sizes was low, which is consistent with lack of significant temporal trends between 2020 and 2023 at 500 m from transect origin for three transects (Section 3.4.5.1 in the 2023 MEEMP main report [WSP 2024]).

Overall, power to detect observed trends was low for observed temporal and spatial effect sizes at all three transects. However, only two of the either observed effects had an absolute value larger than 15% (spatial effect for the East Transects and temporal effect for the West Transect).

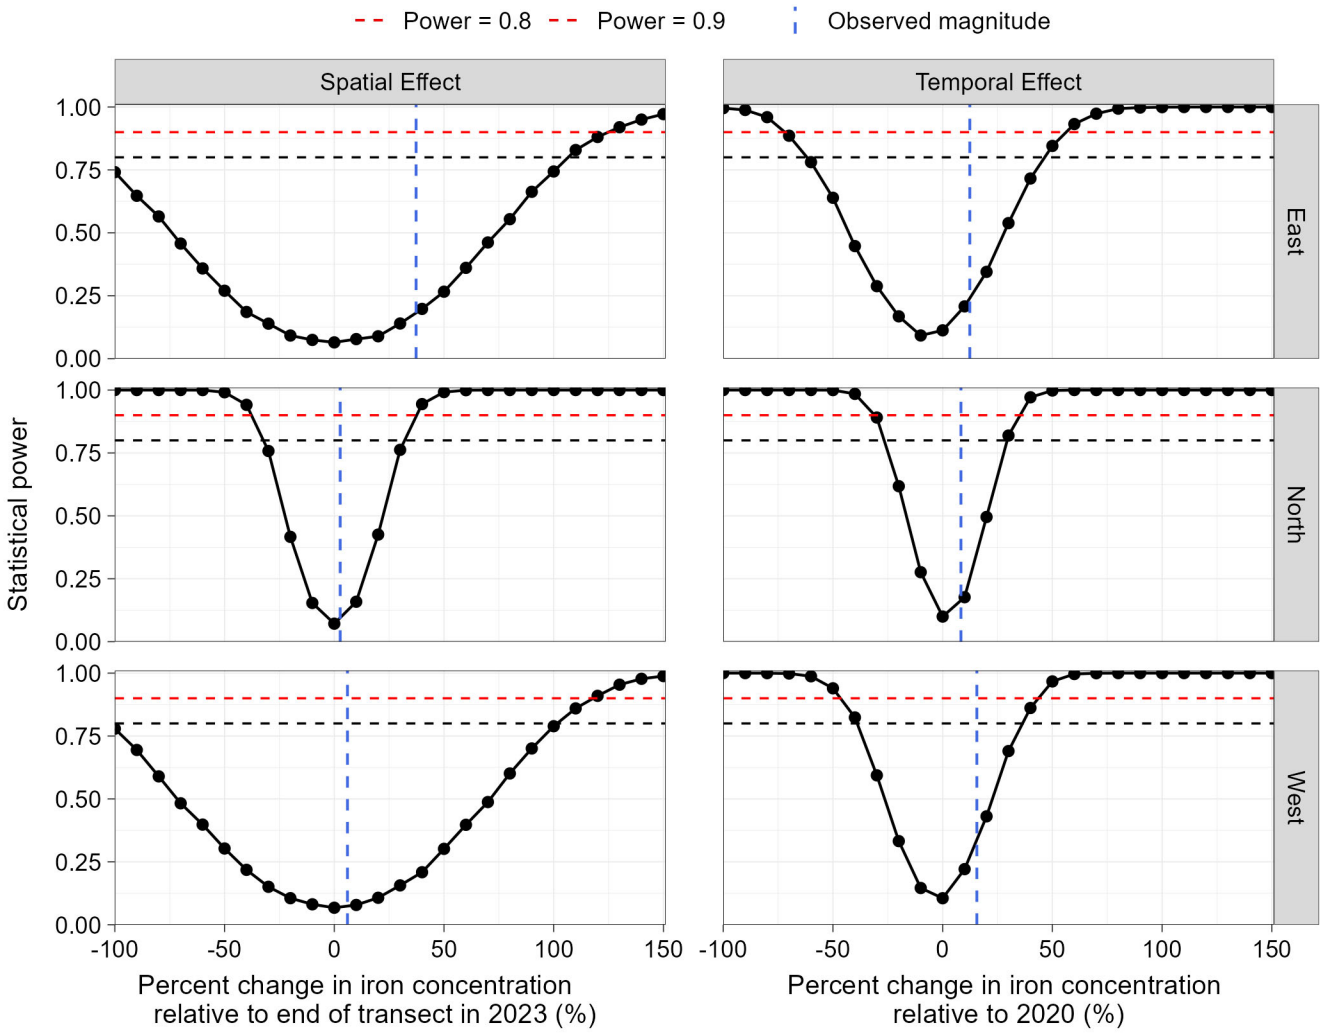

Figure 3G-5: Statistical power of the 2014-2023 iron concentration model to detect a significant spatial trend (left) and a significant difference between 2020 and 2023 (right). Both spatial and temporal effects were tested at 250 m and 500 m from transect origin.

POWER ANALYSIS – SUMMARY

Summary of Findings

- Percent fines, Post-2018 Dataset (i.e., 2019, 2020, and 2023)
  - Spatial effects: sufficient power to detect a spatial effect of scouring (i.e., decrease in fines content) at effect sizes ranging between -70% and -65%. Not sufficient power to detect increases up to +200% for all transects
  - Temporal effects: sufficient power to detect a temporal effect of scouring at effect sizes ranging between -85% and -55% and an increase in fines content ranging between 100% and 150%
- Percent fines, Entire Dataset (i.e., 2014-2020, and 2023)
  - Spatial effects: sufficient power to detect a spatial effect of scouring (i.e., decrease in fines content) at effect sizes ranging between -70% and -65%, and sufficient power to detect increases of +400% at the West Transect, but not the other two transects
  - Temporal effects: sufficient power to detect a temporal effect of scouring at effect sizes between -80% and -70% for the East and North transects, respectively, but not at any negative effect sizes for the West Transect, and sufficient power to detect an increase in fines content ranging between 125% and 500%
- Iron concentrations, Post-2018 Dataset (i.e., 2019, 2020, and 2023)
  - Spatial effects: sufficient power to detect spatial decreases in fines-adjusted iron concentrations at effect sizes of -35% for both Northwest and Northeast transects, but not at any of the negative effect sizes for East and West transects. Also, sufficient power to detect increases in iron concentrations at effect sizes ranging between +30% and +140%
  - Temporal effects: sufficient power to detect temporal decreases or increases at effect sizes between ±15% and ±35%
- Iron concentrations, Entire Dataset (i.e., 2014-2020, and 2023)
  - Spatial effects: sufficient power to detect spatial decreases in fines-adjusted iron concentrations only at effect size of -35% for the North Transect, and not for any of the negative effects at the remaining two transects. Also, sufficient power to detect increases in iron concentrations at effect sizes ranging between +35% and +110%
  - Temporal effects: sufficient power to detect temporal decreases at effect sizes between -65% and -25%, as well as temporal increases at effect sizes between +30% and +50%

Implications of Power Analysis Results

- Overall, the results of the power analysis presented here indicate that analyses of sediment fines had higher statistical power to detect scouring effects than deposition effects. However, large effect sizes were still required to achieve sufficient power, with reductions of 55% or more, depending on the analysis. Analyses of iron concentrations had sufficient statistical power to detect effect sizes of ±35% along the two north transects, but not the East or West transects, due to the low content of fines, a confounding variable.
- Given the low statistical power to detect effect sizes that may be of biological relevance, going forward, it is recommended that conclusions are not made based on strict adherence to statistical significance. Instead, effect size, uncertainty, and statistical significance and power should be considered together before ruling out spatial and temporal changes in percent fines and iron concentrations.

4.0 BENTHIC INFAUNA

4.1 Introduction

This chapter presents the results of the benthic infaunal monitoring program, a component of the larger Marine Environmental Effects Monitoring Program (MEEMP) conducted within the vicinity of Milne Port in Milne Inlet, during the 2023 open-water season. The 2023 MEEMP benthic infaunal sampling program was focused on the 60 stations of the radial transect study design from the 2020 joint sediment and benthic sampling program (Golder 2021).

This component was developed in consideration of the monitoring requirements outlined in the Project Certificate (PC) 005 Conditions described in Chapter 1.0, Table 1-2. PC Conditions related to the benthic infaunal monitoring include PC Conditions No. 76, 87, 99(a), 99(c), and 126.

4.1.1 Objectives

The MEEMP objectives are outlined in Section 1.3 of Chapter 1.0 (Program Overview). The objectives specific to the 2023 benthic infaunal sampling program are:

- Conduct sampling of benthic infauna along four radiating transects in Milne Port to better identify Project-related effects.
- Verify predictions made in the Final Environmental Impact Statement (FEIS) and subsequent addenda (Baffinland 2012, 2013) to the Nunavut Impact Review Board (NIRB) regarding effects on benthic infauna communities, as applicable.
- Collect benthic infauna samples at non-transect stations added to the MEEMP in 2023 to characterize existing conditions to support the assessment of Project-related effects due to the use of larger ore vessels (Baby Cape and Capesize) at Milne Port.
- Recommend any necessary and appropriate changes to the benthic infauna component of the MEEMP for future years.
- Involve Inuit in the marine benthic infaunal monitoring program and include protocols that are responsive to Inuit concerns.

4.2 Study Design

4.2.1 Background

In the 2020 MEEMP Report, Golder (2021) reported that monitoring results to date have not identified Project-induced changes to benthic infauna communities in Milne Inlet. After three consecutive years of implementation, the joint radial benthic and sediment sampling program was moved from an annual to a three-year cycle. The revised monitoring frequency was more comparable with the Federal Metal Mining Environmental Effects Monitoring Program and was commensurate with the lack of directional trends observed from 2018 to 2020 that indicated the Project had not adversely impacted benthic infaunal communities in Milne Inlet.

In 2020, station SW-2 stood out as an outlier with substantially reduced performance indicators (e.g., density, diversity) and a coarser sediment composition relative to other stations along the West Transect and compared to previous years. While it is plausible that this result simply reflects the variability inherent in a dynamic environment, it may also reflect localized physical disturbance at station SW-2 in 2020 resulting from propeller-generated currents (propeller wash) from Project vessels. To determine whether Project activities contributed to these differences, targeted benthic infauna and sediment quality sampling was performed at station SW-2 in 2021 and 2022, with the addition of sampling at adjacent West Transect stations SW-1, SW-3, and SW-4 in 2022. The additional stations were added to continue monitoring for signs of recovery and to better characterize variability in benthic infauna. The 2022 results suggested that the benthic community at SW-2 appeared to have rebounded from the anomaly in 2020 and returned to 2019 levels (WSP 2023). Additionally, in 2021 and 2022, benthic infauna samples were also collected from the first four stations along each of the four transects for the Non-Indigenous and Aquatic Invasive Species (NIS/AIS) monitoring program (Chapter 8.0; WSP 2023).

In 2023, the radial transect sampling program was conducted based on the adjusted monitoring frequency of every three years, 2020 being the last year the full joint sediment and benthic program was sampled. In short, the radial study design involves sampling at 15 stations per transect which are co-located with sediment quality stations (Chapter 3.0) to allow for evaluation of exposure data (sediment quality) in relation to biological variables (benthic infauna community characteristics) (Golder 2021; Figure 3-1). The two Coastal Transects (East and West) and the two Northern Offshore Transects (Northwest and Northeast) are described in detail in Chapter 3.0, Section 3.2.1.

4.2.2 Modifications to the Program (2023)

The radial transect sampling program was designed such that 15 stations along each of the four transects (East, West, Northwest and Northeast) were to be sampled for sediment quality and benthic infauna according to a gradient sampling design. While this was achieved in 2020, in 2023 a total of 41 stations out of the intended 60 stations were sampled due to logistical and time constraints as described in Section 3.2.2. Stations were sampled along each of the four transects for the best spatial coverage in the time allotted.

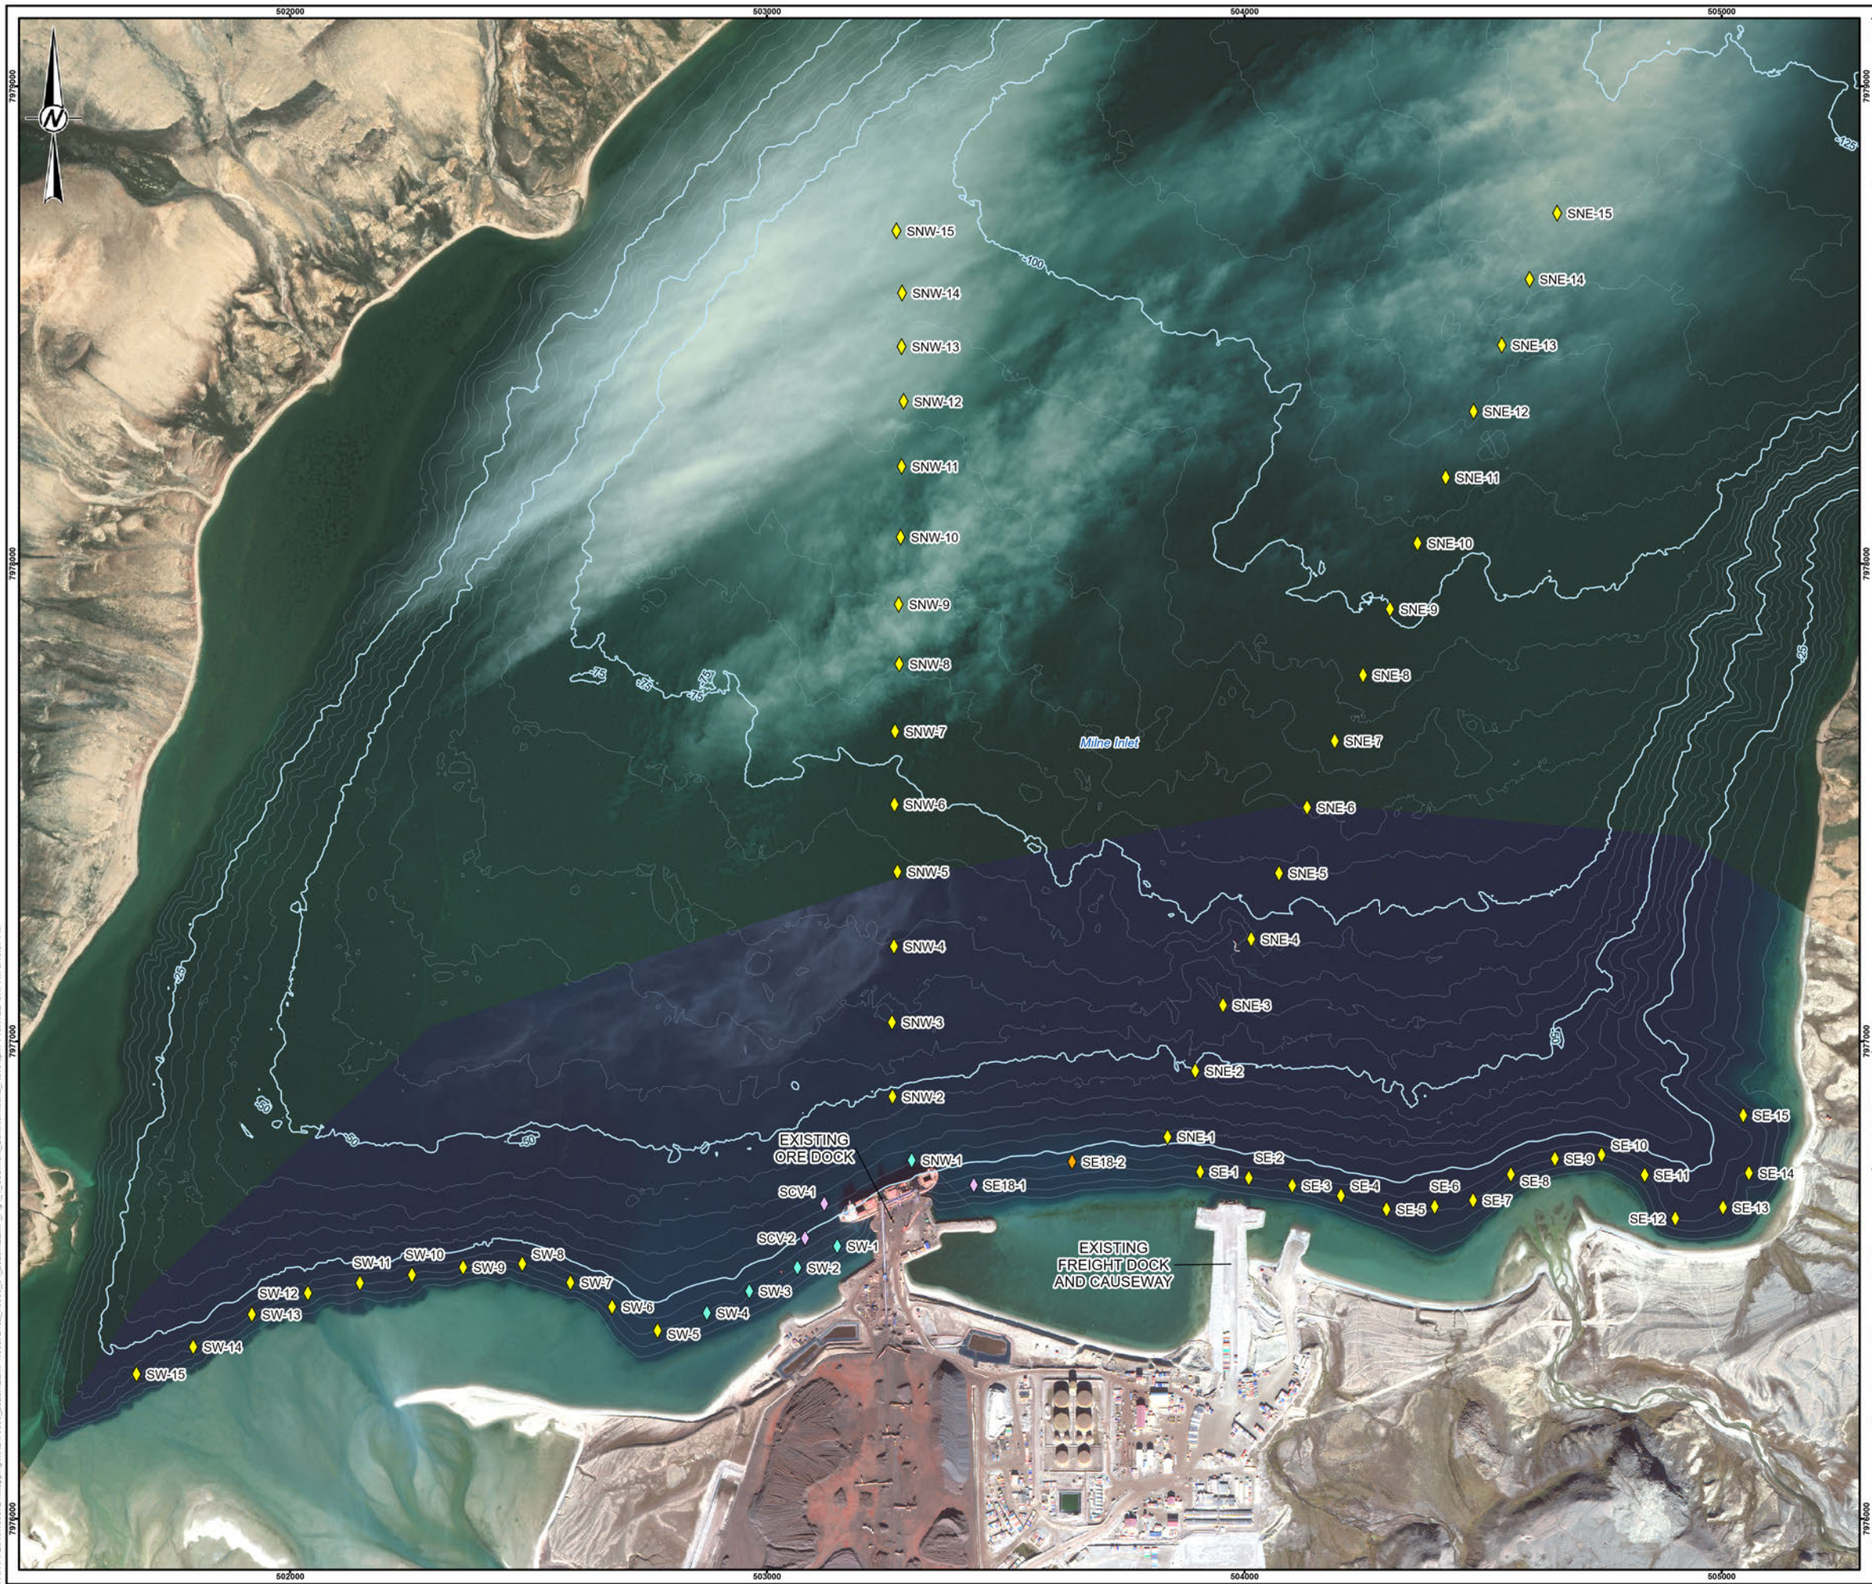
Two new sampling stations, SCV-1, SCV-2, and one preexisting sediment quality station, SE18-1, were added to the 2023 benthic infauna program. These three stations, all located near the Ore Dock, were sampled for benthic infauna as part of the existing conditions sampling program to account for Capesize vessels arriving in Milne Inlet for the first time. The sampling program is further discussed in Section 4.2.3.

In 2023, benthic infauna samples were also collected from six stations for the Non-Indigenous and Aquatic Invasive Species (NIS/AIS) monitoring program (Chapter 8.0) where flagged specimens of concern, or potential NIS/AIS species were collected during the 2019 to 2022 MEEMP and NIS/AIS Monitoring Program surveys (Golder 2020, 2021, 2022; WSP 2023).

4.2.3 Capesize Vessel Existing Conditions Sampling Program

In 2023, NIRB accepted the Sustaining Operations Proposal and issued Amendment 5 of Project Certificate 005. Under Amendment 5, Term and Condition 83(a) required Baffinland to update the marine sediment quality program to reflect the increased use of larger ore vessels at Milne Port. Baffinland committed that stations SW-1 through SW-4, SE18-1, SNW-1, and two new sites (SCV-1 and SCV-2) would be monitored for scouring effects

on sediment and benthic infauna for three years after the initial use of large (Baby Cape and Capesize) ore carriers in fall 2023 (Commitment 10, SOP Technical Comment QIA ME-7(3); NIRB, 2023). Following this three-year period, Baffinland will consider a reduced frequency in sampling at these locations (once every three years) if sediment and benthic conditions at these sites are shown to be stable and within the limits of impact predictions. As the initial Capesize ore carrier use in Milne Port was planned to take place in the late ice-free period of 2023 (29 August 2023), sampling for Capesize vessel effects monitoring commenced in August 2023 (August 4-19, 2023), with the intention of documenting existing conditions for benthic infauna prior to the use of the larger vessels.



Three of the stations to be monitored for Capesize vessel impacts are additional to the 60 stations sampled under the radial transect sampling design. The three stations are SE18-1, which was established in 2019 to maintain consistency with previous MEEMP programs (i.e., previous sediment stations SE-1) and the two new stations established in 2023 specifically for Capesize vessel impacts monitoring (SCV-1 and SCV-2).

4.2.4 Indicators

Indicators and thresholds for the MEEMP program are described in Section 1.4.2. Performance indicators selected to evaluate potential Project-induced changes in benthic infauna communities include density, taxa richness (number of unique taxa present), Simpson's Diversity Index (SDI), and Simpson's Evenness Index (SEI). These indicators are calculated from data collected according to the radial gradient design and analyzed statistically to evaluate Project-related effects within the Milne Inlet study area. The purpose of the radial transect design adopted for the sediment and benthic MEEMP monitoring programs is to assess marine sediment quality and benthic invertebrate communities over time, and similar to previous years, to investigate the potential for project-related effects on these components. The overall trend in benthic communities is compared spatially and temporally examining changes in density, richness, diversity and evenness.

These indicators are described in detail in Section 4.3.2.2.

Along with several other components of the MEEMP, the benthic infauna monitoring program has indicators, thresholds and risk categories that are part of Baffinland's Trigger Action Response Plan (TARP), an adaptive management process. The TARP uses effect indicators that are measured against a series of tiered thresholds (i.e., low, moderate and high-risk thresholds) that are designed to guide short-term and long-term adaptive management strategies as outlined in Baffinland (2023). Baffinland has updated the TARP as part of the revised draft Marine Monitoring Plan (MMP) (Baffinland 2023). The pre-defined actions identified in the TARP describe the responses that Baffinland would implement should the corresponding threshold levels be exceeded and assuming there is some degree of certainty that the measured change is Project-related. As adaptive management is beyond the scope of the present report, only the indicators, risk categories and thresholds are presented here (section 4.3.4).

4.3 Materials and Methods

4.3.1 Field Methodology

The 2023 full-scale radial sampling program involved the collection of benthic infauna samples from 41 stations along four transects and were each co-located with a sediment sampling station (Figure 4-1; Table 4-1). In total, 44 benthic infauna samples were collected for the program (41 transect stations, SE18-1, SCV-1, and SCV-2). Each benthic sample was collected as a composite of three individual grabs using a standard Van Veen sampler with a surface area of 0.1 m². Each grab sample was examined for acceptability using the criteria outlined in Section 3.3.1 in Chapter 3.0 and, upon acceptance, the three individual grab samples were split using a field splitter purpose-built for this program due to the large volume of the Van Veen sampler.

The composite material was gently rinsed with filtered seawater through a 1 cm mesh sieve to initially remove larger organisms that could otherwise become damaged when the composite material was subsequently filtered through a 0.5 mm mesh sieve. The 1 cm sieved sample was either retained as a whole sample, or further split into ½ or ¼, such that a reasonable volume would be submitted to the taxonomy laboratory. Large debris, such as gravel and cobble, were checked for encrusting fauna and included in the sample jar if potential encrusting epifauna were observed. The 1 cm mesh sieved composited material was further split in half, totalling a ¼ field split. The ¼ field split sample was retained and transferred to an aluminum sieving table. The sample was gently rinsed through a 0.5 mm mesh sieve with filtered seawater. A representative photograph was taken of the sieved sample, including a visible sample label (Appendix 4A). Remaining material on the sieve was placed in pre-labeled 1-L wide-mouth high-density polyethylene (HDPE) sample jars and preserved in a 10% buffered formalin solution. The containers were then sealed and inverted several times to promote homogenization with the formalin. Containers were labeled internally and externally with water-resistant labels. The benthic samples were sent to Biologica Environmental Services Ltd. (Biologica) for sorting and taxonomic identifications, as per the previous MEEMP programs. Details on laboratory methods are provided in Appendix 4B.

Notes:

m = metres; UTM = Universal Transverse Mercator

[1] Sample depth was converted to meters chart datum (CD), estimated using tide table for Milne Inlet, Nunavut (https://tides.gc.ca/en/stations/05791 [accessed November 2023]). The negative (-) numbers indicate 'below' CD.

4.3.2 Data Analysis

4.3.2.1 Data Screening

The benthic samples sent to Biologica were sorted using dissecting microscopes at 10-40x magnification. The 1 cm sample fraction was processed based on the field split (no further splitting by Biologica). The fine 0.5 mm sample fraction (¼ field split) was further split into another quarter (¼) by Biologica for a final 1/16 split of the composite sample, using a Caton tray. Each sample was spread evenly on a Caton grid and subsampled via sequential random quadrat sorting. Sorting continued until a minimum ¼ split was reached and taxonomic identifications were carried out to the lowest practicable level.

Taxonomy data provided by Biologica were screened for incidental organisms not considered to be part of the marine benthic community, such as freshwater, terrestrial, planktonic, and parasitic taxa. Meiofauna, such as nematodes, were removed from benthic analysis because these species often fall through the 0.5 mm mesh sieve used to separate benthic infauna from sediments in the field. Nematode species counts would thus not represent true population numbers at each station and could bias station comparisons of total abundance and species diversity. Eliminated taxa, not expected to have significant direct exposure to sediments, included Nematoda (meiofauna), Chironomidae (subfamily Diamesinae, Chironominae, Orthocladiinae, Tanypodinea and Tipulinae,

brackish/freshwater), Diptera (freshwater), Arachnida (freshwater), fish (Cottidae, Ammodytidae, Stichaeidae and Zoarcidae), Ostracoda (planktonic), Copepoda (parasitic and planktonic), Ctenophora (planktonic), and Insecta (terrestrial) taxa.

4.3.2.2 Benthic Community Performance Indicators

A description of performance indicators (organism density, taxa richness, Simpson's Diversity Index, Simpson's Evenness Index) selected to evaluate potential Project-induced changes in benthic infauna communities is provided below.

Organism Density

Total invertebrate density was calculated as the number of organisms per square metre (organism/m^2) for each station. The surface area of the Van Veen (0.1 m^2) was multiplied by three to account for the three composite grab samples using the following equation:

$$Density = \frac{number\ of\ organisms\ (org)\ per\ station}{(grab\ sampler\ area * 3\ composites)}$$

Taxa Richness

Taxa richness is the total number of unique[1] taxa per station and provides an indication of the diversity of benthic invertebrates in an area; a higher richness value typically indicates a healthier and balanced community.

Simpson's Diversity Index (SDI)

Simpson's Diversity Index (SDI) measures the proportional distribution of organisms in the community. The SDI considers the abundance patterns and taxonomic richness of the community. Certain conditions may favour one taxa over another, resulting in the community being dominated by a few taxa, which is reflected in decreased diversity (Simpson 1949). The SDI value ranges between zero and one, where lower values indicate a less diverse community and higher values indicate a more diverse community. The SDI was calculated using the formula provided by Krebs (Krebs 1999):

$$SDI = 1 - \sum_{i=1}^{S} (p_i)^2$$

Where:

- SDI = Simpson's diversity index
- S = the total number of taxa
- p_i = the proportion of the i^{th} taxon

[1] Did not include higher order taxa for which there exists a lower order identification. For example, does not include *Ophiura* sp. if *Ophiura robusta* is found in the same sample.

Simpson's Evenness Index (SEI)

Simpson's Evenness Index (SEI) is a measure of the relative abundance of the different taxa contributing to richness, or in other words, how evenly the total invertebrate density is distributed among the taxa present at the station. SEI compares the observed community to a hypothetical community, which consists of the same number of taxa that are equally abundant. The SEI is included along with the SDI to provide context as to whether richness or the distribution of total density among taxa is driving the SDI values. The SEI is also expressed as a value between one and zero, with one representing high evenness (i.e., equal numbers of all taxa present in a sample) and zero representing low evenness (i.e., a high degree of dominance by one or a few taxa). Communities with a high degree of dominance by one or a few taxa are often referred to as "stressed" and may reflect the influence of natural and/or anthropogenic stressors.

The SEI values were calculated using the following formula (Smith and Wilson 1996):

$$SEI = 1 / \sum_{i=1}^{S} (p_i)^2 / S$$

Where:

- SEI = Simpson's evenness index
- S = the total number of taxa
- p_i = the proportion of the i^{th} taxon

4.3.2.3 Statistical Analysis

Benthic infauna data collected during the 2018 to 2020 and 2023 programs, which collectively comprise the Post-2017 Dataset, were analyzed to assess spatial and temporal gradients in benthic indicators[2]. The radial transect program was implemented in those MEEMP years and was the focus of the statistical analysis in this report. Accordingly, data collected during targeted sampling at SW-2 and at surrounding stations in 2021 and 2022 were not included in the analysis.

Modeling the benthic infauna data required the use of a distance variable as a predictor in the spatio-temporal models. Prior to 2020 (Golder 2021), distance from the Ore Dock area was used; however, in line with analysis performed after the collection of 2020 data to standardize the values and improve interpretation, a single origin point was used for spatio-temporal modelling. This point (the transect origin), an imaginary intersection between the East, West, and Northwest transects, was determined to be at coordinates of -80.905917°, 71.889649°, and was at the center of the Ore Dock area. All distances reported in the analyses were calculated as straight-line distances from each sampling location to this point of origin.

Statistical analyses were conducted using generalized linear modelling and included main effects of distance from the Ore Dock area, year (as a categorical variable), transect, all possible interactions among the three variables, and percent fines. Model residuals were examined to identify departures from generalized linear regression

[2] Prior to statistical analysis the, SDI, and SEI indicators were recalculated for the 2018 benthic dataset to allow for a consistent dataset for the temporal comparisons.

assumptions (as applicable): residual distribution, homoscedasticity (equal variances), and linearity in predictors (lack of structure in residuals).

In order to account for nonlinear relationships between response variables and distance from transect origin as well as percent fines, these predictors were modelled using natural splines, a form of non-linear regression. The number of spline knots was determined using Akaike information criterion (AIC), where models with the lowest AIC was selected as the preferred model. Statistical outliers and influential points were identified and removed during the analysis but were shown on the plots depicting raw values and model predictions for transparency. Following regression analysis, multiple comparisons were performed to assess differences in modelled benthic infauna indicator variables among years at select distances along the transects. These multiple comparisons were performed at distances of 250 m, 500 m, 1,000 m, and 1,500 m along each transect for each year, as applicable based on the length of the transect. In addition, multiple comparisons, with familywise p-value adjustments, were performed at each distance across sampling years, in order to evaluate temporal variation in response variables at distance.

The analyses of benthic fauna total density, richness, SDI, and SEI were performed in the statistical environment R v.4.3.2 (R 2023), using the packages “car” (Fox and Weisberg 2019), “emmeans” (Lenth 2020), and “glmmTMB” (Brooks et al. 2017).

Inverse Distance Weighting (IDW) of Benthic Infauna Diversity Metrices

An Inverse Distance Weighting (IDW) interpolation method in ArcGIS was used to create Figures 4-3 (total density), 4-5 (total richness), 4-7 (SDI), and 4-9 (SEI) to provide a visual depiction of the spatial variability in these benthic community indicators across the study area, as informed by the results of the radial gradient study design in 2023. IDW is a deterministic interpolation method that assumes the variable being interpolated decreases in influence (its weight) with increased distance from its sample location, and conversely, that an interpolated value is most influenced by the known sample(s) closest to it.

4.3.3 Quality Management

Quality assurance and quality control (QA/QC) procedures were applied to the field collection, data analysis, and reporting tasks within the benthic infauna component to verify that the data presented were valid and of acceptable quality to address objectives stated in Section 4.1.1.

4.3.3.1 Field QA/QC

QA measures undertaken to confirm benthic infauna sample integrity are the same as those described for sediment quality as noted in Section 3.3.1. Each grab sample was examined for acceptability based on the following criteria:

- The sampler was fully closed.
- There was adequate penetration depth (i.e., sediment volume greater than 25% full).
- The sample did not appear overfilled or disturbed, and the sample did not appear to have been collected on an angle.

- The sampler did not appear to be leaking sediment at a substantial rate (i.e., the top of the sediment profile did not appear to be sloping inwards).

4.3.3.2 Laboratory and Data Analysis QA/QC

Biologica's laboratory QA/QC measures included an assessment of sorting recovery, identification error, and precision/accuracy of sub-sampling. Laboratory procedures included sample sorting measures, spot-checks of portions of samples by a second sorter to ensure all organisms have been removed from the sample, preliminary counting of major groups, and collaborative identification to accurately identify species to their lowest practicable level. Further detailed discussion of the laboratory QA/QC procedures used by Biologica and the findings of their QA/QC assessment are provided in their laboratory reports in Appendix 4B.

Benthic data received from Biologica were reviewed upon receipt to verify that specified laboratory data quality objectives were met. No inconsistencies were noted that required follow up with the laboratory. Screening of the benthic data and calculation of the benthic indicators were reviewed by a second biologist for accuracy.

4.3.4 TARP Assessment

As part of applying the Trigger Action Response Plan benthic infauna performance indicators were screened against condition status/thresholds in 2023, in order to assess risk levels for each performance indicator (Table 4-2).

Table 4-2: Marine Environment TARP Framework for Benthic Infauna

Component	Performance Indicators	Condition Status/Threshold		
		Low Risk	Moderate Risk	High Risk
Benthic Infauna	• Density • Taxa Richness • Simpson's Diversity Index • Simpson's Evenness Index	• Spatial and temporal trend analysis for density or taxa richness suggest a pattern indicative of Port-related effects beyond FEIS predictions. AND • Low Risk Status/Threshold is triggered for sediment.	• Spatial and temporal trend analysis for density and taxa richness suggest a pattern indicative of Port-related effects beyond FEIS predictions. AND • Moderate Risk Status/Threshold is triggered for sediment.	• To be determined based on outcome of moderate response investigations.

4.4 Results

Benthic invertebrate infauna samples were collected from 44 stations, with 41 arranged along four transects (i.e., East, West, Northwest, and Northeast) extending out from the Ore Dock and three additional non-transect stations located within the vicinity of the Ore Dock. Photographs are provided in Appendix 4A. The laboratory methods report, and results provided by Biologica are located in Appendix 4B and 4C, respectively. Summary results of the taxonomic analysis of benthic infauna are available in Appendix 4D.

4.4.1 2023 Benthic Invertebrate Community Indicators

Benthic invertebrate community indicators used to evaluate infauna along the four transects are depicted in Figure 4-2 to 4-9 and summary statistics (mean, median, minimum, maximum, count, standard deviation, and standard error) for those indicators are presented in Appendix 4D. An evaluation of the four indicators is provided below with a focus on mean +/- SE values.

- **Total Density**— Densities were greater and more variable along the East Transect (22,274 ± 2,749 org/m^2) and West Transect (13,195 ± 1,842 org/m^2) compared to the Northwest and Northeast Transects (6,343 ± 920 org/m^2 and 6,532 ± 942 org/m^2, respectively) (Figure 4-2). As these mean values indicate and as shown on Figure 4-3, total densities were higher along the East Transect compared to the West Transect.
- **Richness** (i.e., number of unique taxa) — On average, richness was higher along the East Transect (60 ± 3) compared to the other three transects Figure 4-4), which had similar mean values (Appendix 4D). As a result of higher variability in richness along the West Transect, the mean was lower than the East Transect but the range of richness values was higher than the offshore transects.
- **Simpson's Diversity Index (SDI)** — Communities along all four transects were diverse with relatively high SDI values. The lowest mean SDI value was calculated for the East Transect (0.89 ± 0.03), driven by a lower SDI value at SE-11 (Figure 4-6 and Figure 4-7). The offshore transects were less variable in diversity compared to the coastal transects.
- **Simpson's Evenness Index (SEI)** — SEI was somewhat variable along the four transects but was typically higher along the Northwest (0.35 ± 0.04) and Northeast Transects (0.33 ± 0.04) when compared to the East (0.19 ± 0.02) and West Transects (0.13 ± 0.02) (Figure 4-8 and Figure 4-9). On the scale of 0 to 1, evenness values across all transects were reasonably low as shown on Figure 4-9, indicating that the distribution of taxa within the community was relatively uneven, and that a small number of taxa contained most of the organisms. These results are reflective of the natural community.

4.4.2 2023 Relative Densities of Benthic Invertebrate Taxa

Benthic communities sampled at stations along the offshore and coastal transects were mainly dominated by Polychaeta (26 to 93%) followed by Malacostraca, then ostracods and bivalves (Figure 4-10). The polychaete species *Nereimyra aphroditoides* and genus *Pholoe* spp. accounted for approximately 11% and 12%, respectively, of total density across the transects (Appendix 4C). The two exceptions were station SE-11 on the East Transect which was dominated by Malacostraca, and SNW-2 on the Northwest Transect which had approximately equal distribution of polychaetes, ostracods, Malacostraca, and bivalves. Relative dominance by Malacostraca at SE-11 was the result of a large influx of Malacostraca compared to other stations and not a decrease in polychaetes or other taxa, which were largely comparable to other stations. Conversely, changes in relative abundance at SNW-2 were driven mainly by a decrease in polychaete density compared to adjacent stations. These differences likely reflect natural variation in the benthic infaunal community.

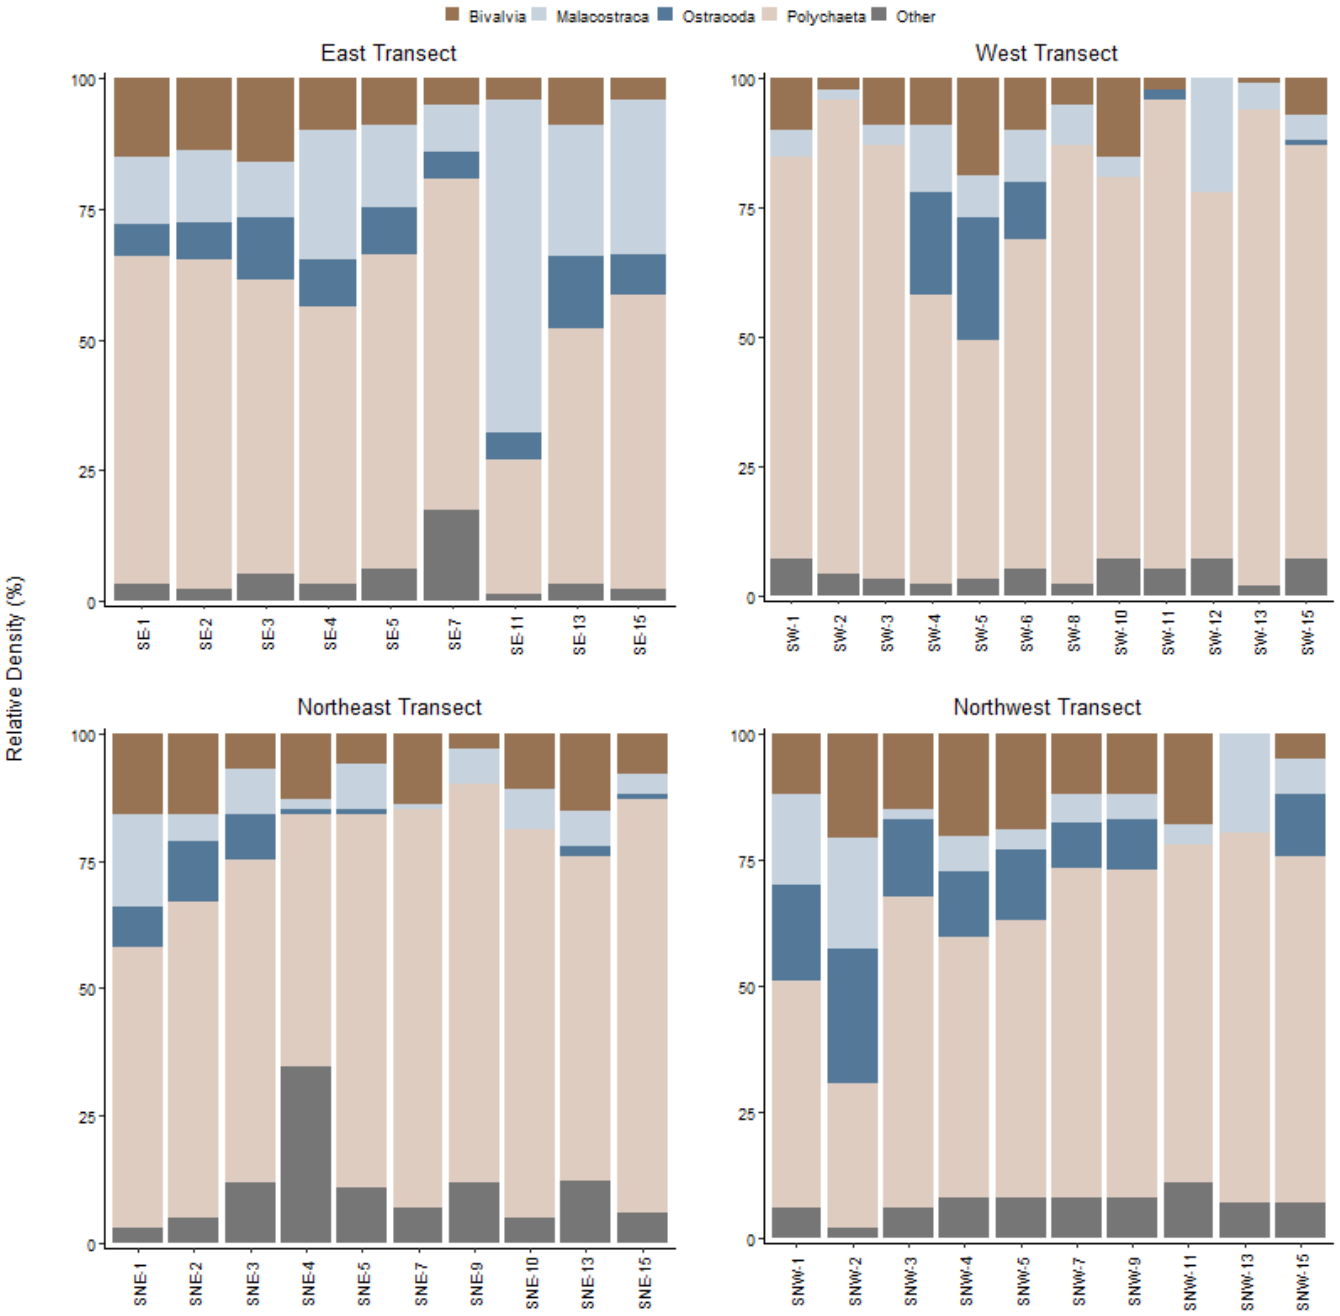

Figure 4-10: Relative Density of Major Benthic Infauna Taxa from Sampling Stations along the Four Radial Transects Extending from the Ore Dock Area, Milne Port, 2023.

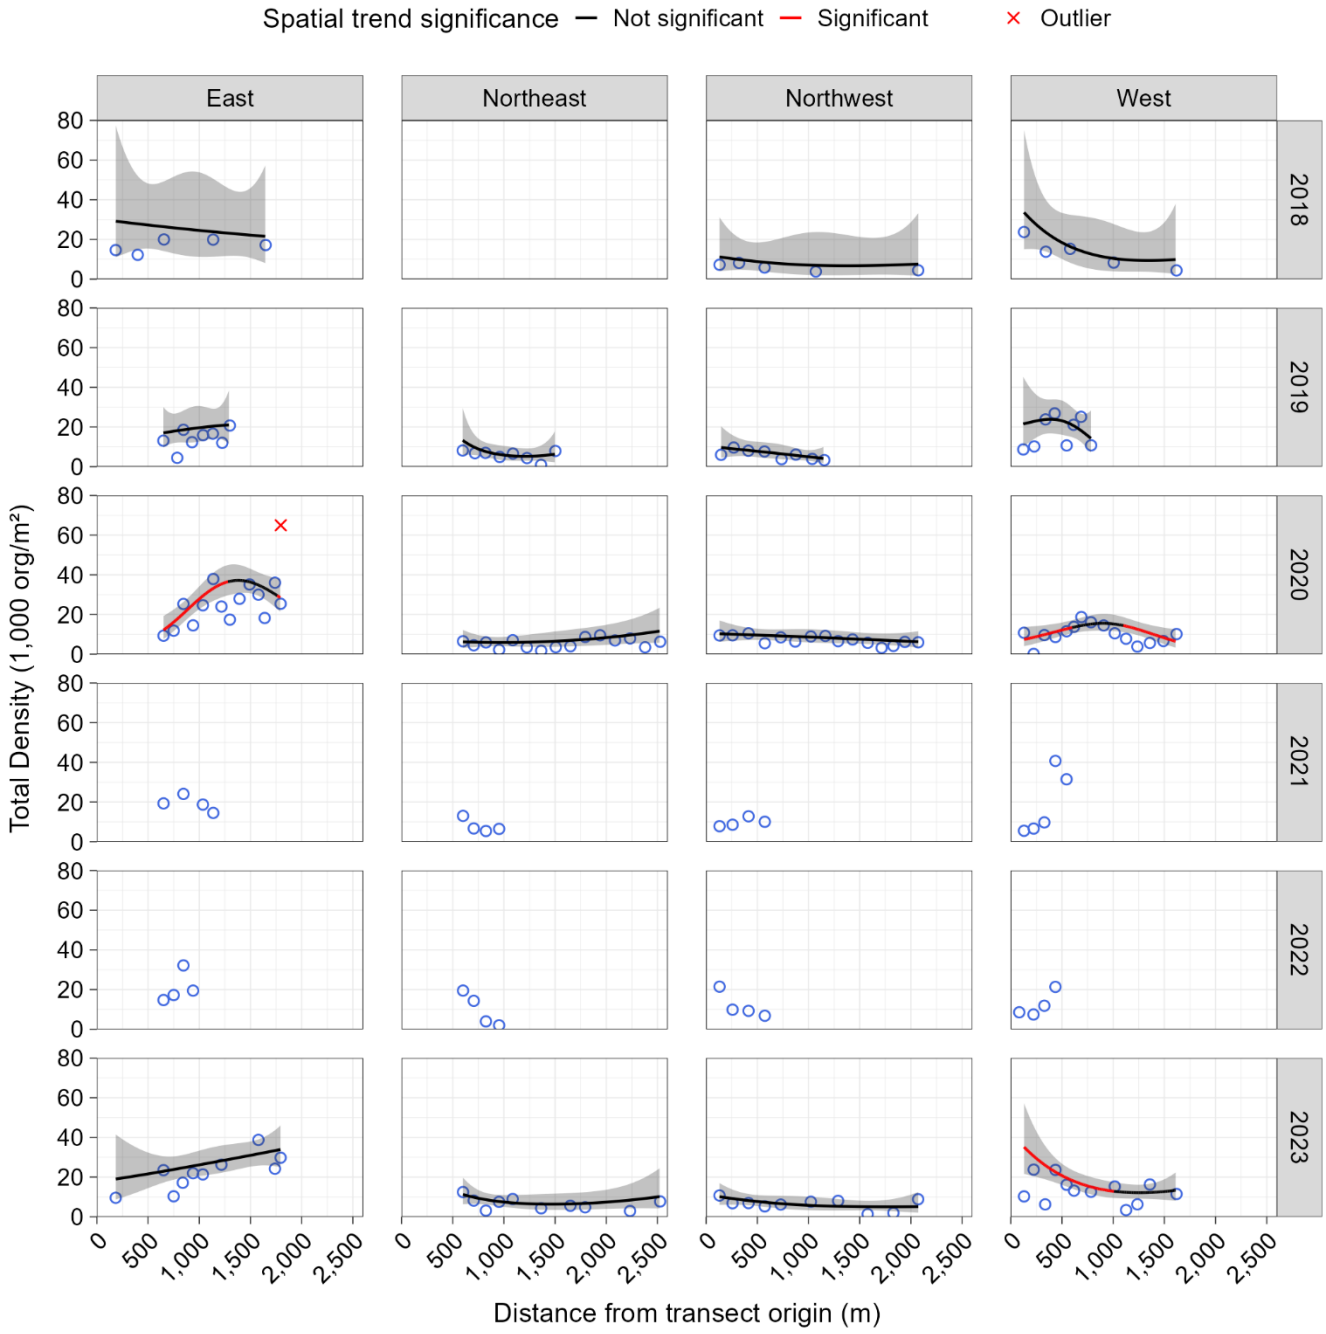
4.4.3 Statistical Comparisons of Community Indicators

Generalized linear models were used to evaluate spatial and temporal trends in community indicators (i.e., total density, richness, SDI, and SEI) in Milne Port from 2018 to 2023. The main effects of each model included distance from the Ore Dock area, year (as a categorical variable), transect, and all possible interactions between these three variables. Additionally, a main effect of percent fines was used to account for the ecological relationship between total density and habitat variation (with percent fines being the dominant habitat variable). Both distance from the Ore Dock area and percent fines were modelled using non-linear terms (i.e., natural splines) to account for non-linearity in trends of total density relative to distance and habitat variability. Results of the generalized linear models are presented in Table 4-2. Post hoc marginal mean trend evaluations are presented in Tables 4-3 to 4-10. The interpretation of the results focused on post hoc comparisons within 2023 and between 2023 and previous monitoring years; however, results for all comparisons are included herein.

4.4.3.1 Total Density

The total density three-way interaction was not significant (Table 4-2); however, the two-way interactions between distance from the Ore Dock area and transect, as well as between distance from the Ore Dock area and year were statistically significant, indicating differences in the relationship between total density of benthic infauna taxa and distance among transects, as well as among years (Table 4-2). Total benthic infauna density was also significantly related to percent fines.

Overall, in 2023, infaunal density was comparable to previous years. There was an approximately linear relationship between density and distance from the Ore Dock area along all transects, except for the West Transect in most years and the East Transect in 2020 (Figure 4-11). There were no significant spatial trends in density along the offshore transects with distance in 2023, or significant differences between years for most combinations of distances and transects. Some significant spatial trends and interannual differences were identified for the coastal transects, as follows:



- In 2023, total density displayed a significantly decreasing trend with increasing distance from the Ore Dock area along the West Transect (250 m to 1,000 m; Figure 4-11). Mean infaunal densities were significantly higher at 250 m and 500 m, compared to 1,000 m (Table 4-3), likely due to the influence of Phillips Creek. No other spatial trend in benthic infauna total densities were observed in 2023.
- Although some interannual variability was observed within and among transects (Figure 4-12), significant interannual differences in total density were only observed along the East Transect at 500 m (2020 < 2018) and The West Transect at 250 m (2020 < 2018, 2020 < 2019, 2020 < 2023) and 500 m (2020 < 2019, 2020 < 2023; Figure 4-12; Table 4-4).

Statistical power was sufficient to detect a reduction of 72–85% in density along all four transects between 1,000 m from transect origin and the first sampling station, or an increase of 105–200%, depending on the transect (Appendix 4E). None of the observed effect sizes had sufficient statistical power. For the temporal effects, statistical power was sufficient to detect decreases in density ranging between -90% and -67% for three of the transects or an increase at effect sizes ranging between 99% and 290% for three of the transects (Appendix 4E). The large effect sizes required to obtain sufficient power for increasing density, especially for the temporal effects, was due to density values observed in 2020 being small, requiring increases of large percent values to detect a significant difference from the simulated 2023 density values.

Table 4-2: Summary of the Benthic Infauna Regression Model Results (2018-2023; four monitoring years)

Parameter	DF	Chi-Square	P-value

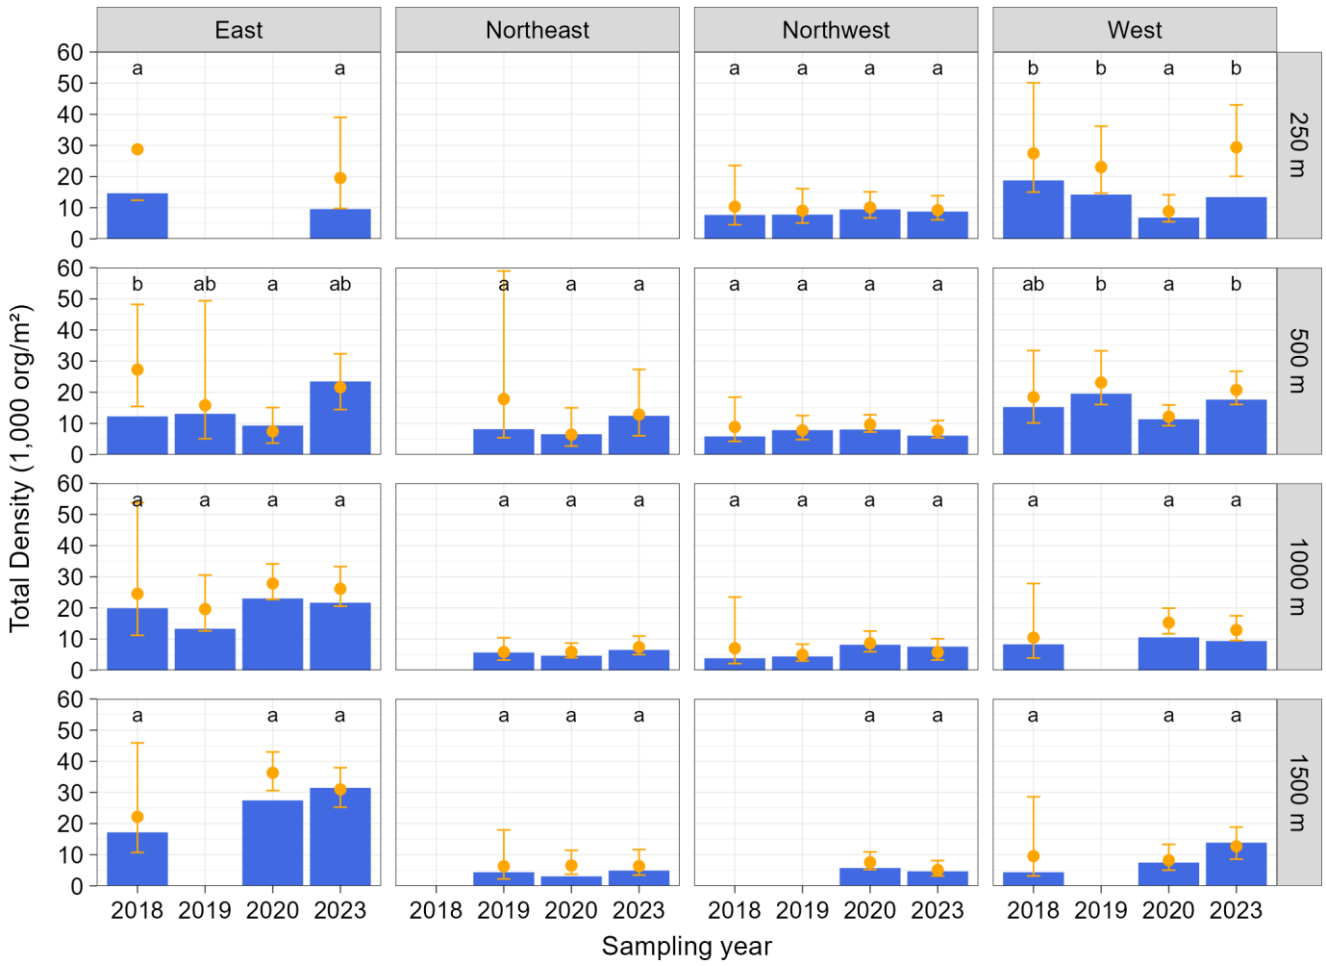
Distance from Ore Dock Area[(a)] × Year	6	2.75	0.84
Distance from Ore Dock Area[(a)] × Transect	6	8.8	0.185
Year × Transect	8	15.5	0.050
Distance from Ore Dock Area[(a)] × Year × Transect	16	16.43	0.423

Notes: Cells highlighted in **blue** indicate significant effects (p-value <0.05), while **bold** values indicate statistically significant effects in the face of significant, higher-order terms – these values should not be directly interpreted. In instances of significant interaction terms, the main effects cannot be interpreted. Refer to post hoc multiple comparison tables. DF= degrees of freedom; ns = natural spline.
(a) Modelled using a natural spline to account for non-linear relationships between endpoint and variable.



Measured total infaunal density (open circles) and mean densities (lines) plus 95% confidence intervals (grey ribbons) are shown for each sampling year and transect. Red lines indicate a significant spatial trend, black lines indicate no significant trend. No data were collected in 2019 along the Northwest Transect at farther distances, precluding comparisons to 2018, 2020, and 2023. Data collected in 2022 (n = 16) were part of the Aquatic Invasive Species (AIS) surveys, not part of the radial study design, and are included for completeness.

Figure 4-11: Spatiotemporal Trends in Benthic Infauna Total Density Relative to Distance from the Ore Dock Area, 2018 – 2023.

Table 4-3: Multiple Comparisons of Benthic Infauna Total Density between Distance from Ore Dock Area within Years, 2018 – 2023

Transect	Year	Distance From Ore Dock		
		250 m vs 500 m	500 m vs 1000 m	1000 m vs 1500 m
Total Density				
East	2018	0.998 (5%)	0.990 (11%)	0.995 (10%)
	2019	-	0.991 (-19%)	-
	2020	-	**0.002 (-73%)**	**0.019 (-24%)**
	2023	0.933 (-10%)	0.832 (-17%)	0.494 (-14%)
Northeast	2018	-	-	-
	2019	-	0.491 (206%)	1.000 (1.6%)
	2020	-	0.998 (8%)	0.983 (-6.2%)
	2023	-	0.634 (73%)	0.659 (21%)
Northwest	2018	0.963 (17%)	0.951 (25%)	0.997 (5.5%)
	2019	0.930 (17%)	0.488 (56%)	-
	2020	0.983 (5.0%)	0.919 (11%)	0.510 (16%)
	2023	0.688 (20%)	0.471 (33%)	0.860 (14%)
West	2018	0.550 (49%)	0.297 (76%)	0.992 (17%)
	2019	1.00 (0%)	-	-
	2020	0.144 (-27%)	0.489 (-20%)	0.315 (52%)
	2023	**0.033 (42%)**	**0.005 (61%)**	0.999 (2.7%)

Notes: Values are shown as: P-value (Effect Size, %). Cells highlighted **blue** indicate statistically significant results (p-value <0.05). Positive effect sizes indicate total density is higher at the distance closer to the Ore Dock area (i.e., total density decreases with increasing distance). Negative effect sizes indicate total density is lower at the distance closer to the Ore Dock area (i.e., total density increases with increasing distance).
- = Data not available for comparison.

No data were collected in 2019 along the Northwest Transect at farther distances, precluding comparisons to 2018, 2020, and 2023. Measured total density (blue bars) and marginal means ± 95% confidence intervals (orange circles, error bars) are indicated for each sampling year and distance.

Figure 4-12: Interannual Differences in Benthic Infauna Total Density Relative to Distance from the Ore Dock Area, 2018-2023.

Table 4-4: Post hoc Multiple Comparisons of Benthic Infauna Total Density between Years within Distances from the Ore Dock Area, 2018-2023.

Transect	Distance From Ore Dock Area	Post hoc Comparisons					
		2018 vs 2019	2018 vs 2020	2018 vs 2023	2019 vs 2020	2019 vs 2023	2020 vs 2023

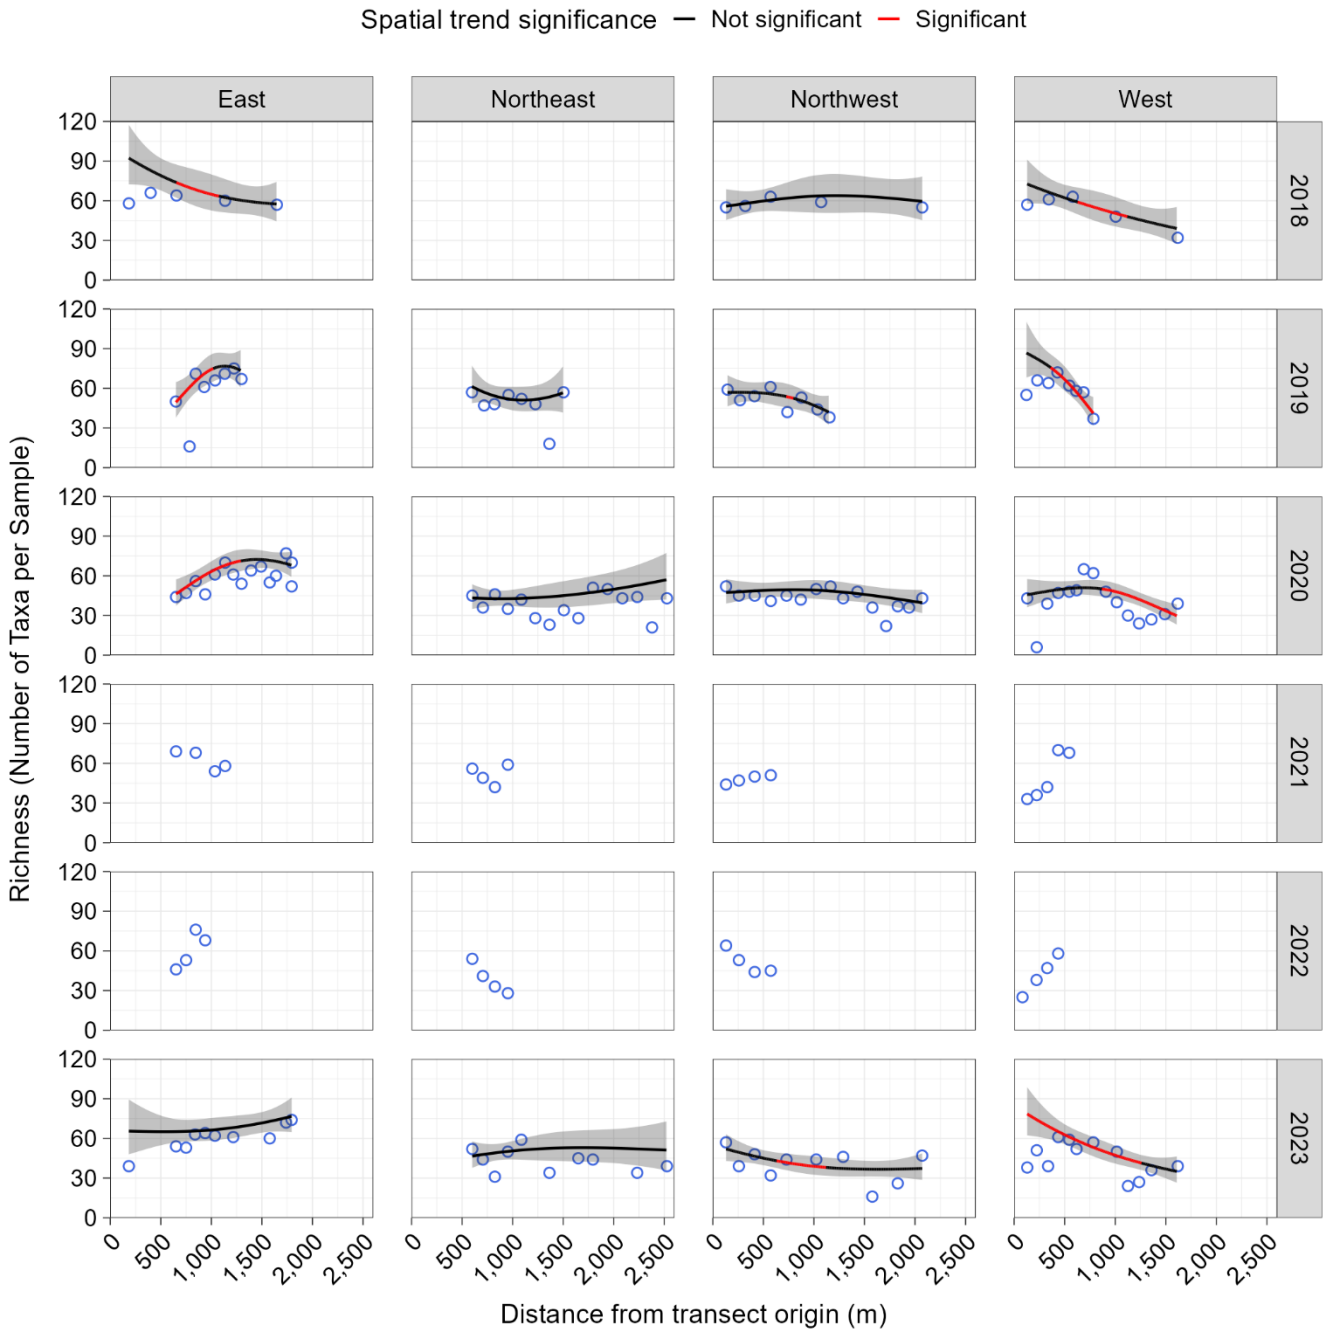
	1500 m	-	0.398 (-64%)	0.663 (-40%)	-	-	0.455 (15%)
Northeast	250 m	-	-	-	-	-	-
	500 m	-	-	-	-	-	-
	1000 m	-	-	-	0.999 (-1%)	0.761 (-27%)	0.638 (-26%)
	1500 m	-	-	-	0.997 (-4%)	1.00 (-1%)	0.996 (3%)
Northwest	250 m	0.994 (12%)	1.00 (3%)	0.995 (11%)	0.991 (-11%)	1.00 (-2%)	0.990 (9%)
	500 m	0.991 (12%)	0.997 (-9%)	0.986 (13%)	0.865 (-24%)	1.00 (1%)	0.743 (20%)
	1000 m	0.951 (30%)	0.989 (-22%)	0.990 (18%)	0.268 (-74%)	0.979 (-16%)	0.586 (33%)
	1500 m	-	0.981 (-12%)	0.888 (25%)	-	-	0.292 (33%)
West	250 m	0.966 (16%)	**0.014 (68%)**	0.997 (-7%)	**0.011 (62%)**	0.801 (-27%)	**<0.001 (-233%)**
	500 m	0.919 (-26%)	0.589 (34%)	0.984 (-13%)	**0.027 (47%)**	0.962 (10%)	**0.008 (-71%)**
	1000 m	-	0.745 (-46%)	0.915 (-23%)	-	-	0.687 (16%)
	1500 m	-	0.966 (14%)	0.879 (-33%)	-	-	0.348 (-55%)

Notes: Values are shown as: P-value (Effect Size, %). Cells highlighted **blue** indicate statistically significant results (p-value <0.05). Positive effect sizes indicate total density is higher in the past. Negative effect sizes indicate total density is higher in the more recent year.
- = Data not available for comparison.

4.4.3.2 Richness

The richness three-way interaction between distance from the Ore Dock area, year, and transect was statistically significant for richness (Table 4-2), indicating significant interannual differences in the relationship between richness and distance from the Ore Dock area along different transects. Percent fines was also a statistically significant predictor of benthic infauna richness (Table 4-2).



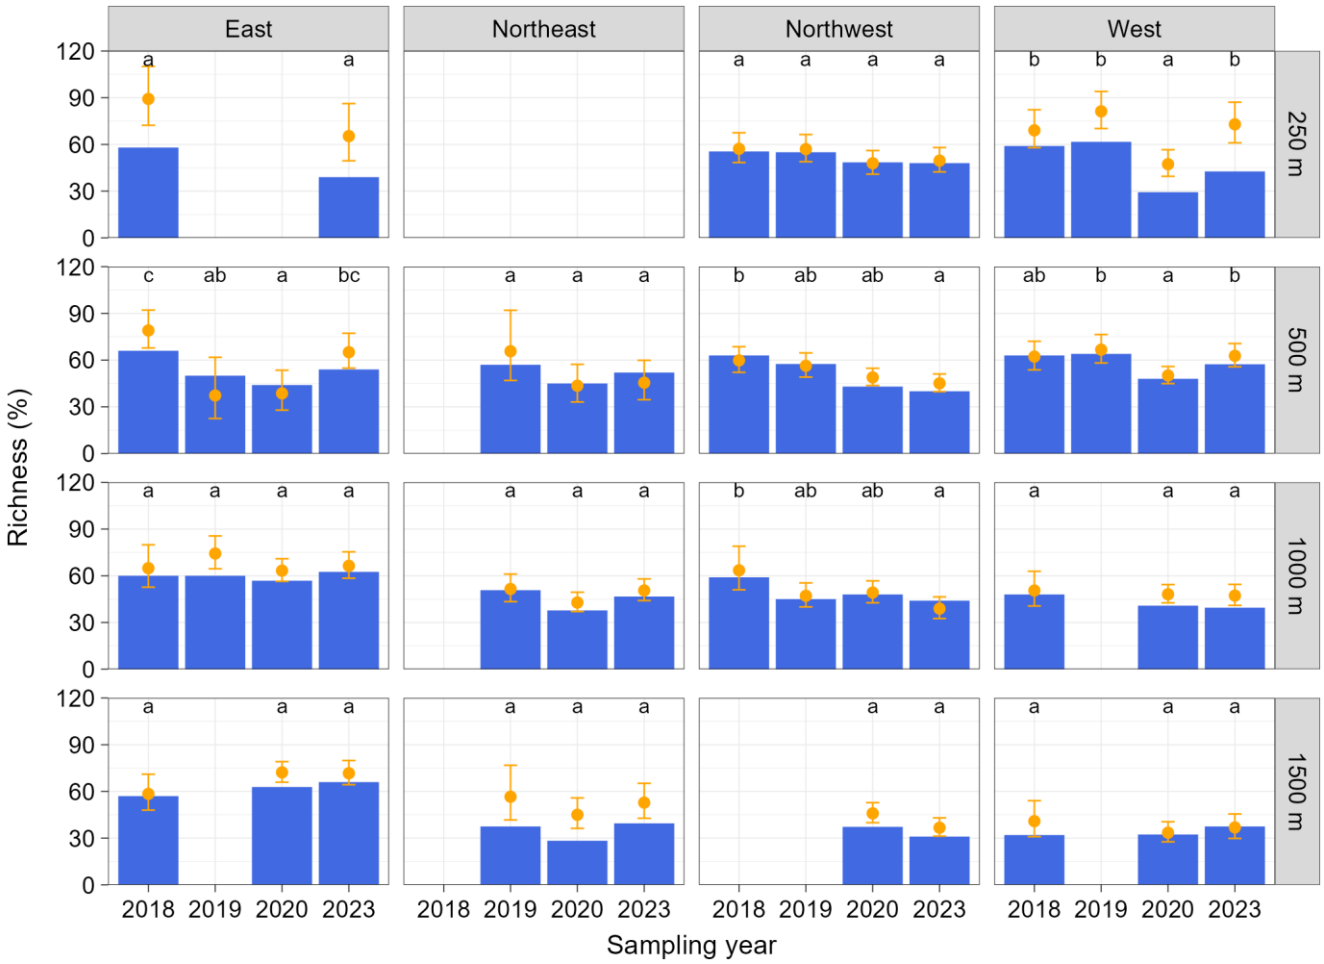
For the most part, benthic invertebrate richness had a non-linear relationship with distance from the Ore Dock area along both offshore and coastal transects (Figure 4-13). Although there were some significant differences among years as described below, no consistent differences (i.e., trends) were found among sampling years.

- **East Transect**—Richness decreased with distance from the Ore Dock area in 2018 but increased with distance in all subsequent years (Table 4-5; Figure 4-13). Richness was significantly higher at 1,000 m compared to 1,500 m and at 1,000 m compared to 500 m in 2020 (Table 4-5). The only significant differences between years were at 500 m from the Ore Dock area, where richness in 2018 was significantly higher compared to 2019 and 2020, and richness in 2023 was significantly higher compared to 2020 (Figure 4-14; Table 4-6).
- **West Transect**—Richness generally decreased with distance from the Ore Dock area in all years (Figure 4-13). In 2023, richness decreased significantly with increasing distance from the Ore Dock area (Table 4-5).

The trend of significantly higher richness near the Ore Dock area compared to later in the transect was seen in most years to various degrees (Table 4-5). At 250 m and 500 m from the Ore Dock area, 2023 richness was significantly higher than 2020 but not significantly higher than in other years (Figure 4-14; Table 4-6).

- **Northwest Transect**—Richness spatial trends with increasing distance were not consistent between years (Figure 4-13). There were no significant differences in richness along the transect within any year (Table 4-5). In 2023, richness was significantly lower than 2018 at 500 m, 1000 m, and 1,500 m from the Ore Dock area, but not significantly lower than 2020 at any distance along the transect (Figure 4-14; Table 4-6).
- **Northeast Transect**—Richness spatial trends with increasing distance were not consistent between years (Figure 4-13). There were no significant differences in richness along the transect within or between years (Figure 4-14; Table 4-5; Table 4-6).

Statistical power was sufficient to detect a reduction of 45–52% or an increase of 57–75% in species richness along each transect between 1,000 m from transect origin and the first sampling station (Appendix 4E). Only one observed difference was larger than these effect size cutoffs, with an increase of 109% in richness at the West Transect. For the temporal effects, power was sufficient to detect a reduction of 37–75% or an increase of 42–120% in species richness (Appendix 4E). Observed effect sizes ranged from +4% to +69%, indicating either no change or an increase in richness between 2020 and 2023 in proximity to transect origins.



Measured total infaunal taxa richness (open circles) and mean richness (lines) plus 95% confidence intervals (grey ribbons) are shown for each sampling year and transect. Red lines indicate a significant spatial trend (p-value <0.05), black lines indicate no significant trend. No data were collected in 2019 along the Northwest Transect at farther distances, precluding comparisons to 2018, 2020, and 2023. Data collected in 2021 and 2022 (n = 17 and n = 16, respectively) were part of the Aquatic Invasive Species (AIS) surveys, not part of the radial study design, and are included for completeness.

Figure 4-13: Spatiotemporal Trends in Benthic Infauna Taxa Richness Relative to Distance from the Ore Dock Area, 2018 – 2023.

Table 4-5: Multiple Comparisons of Benthic Infauna Taxa Richness between Distances from Ore Dock Area within Years, 2018 – 2023

Transect	Year	Distance From Ore Dock Area		
		250 m vs 500 m	500 m vs 1000 m	1000 m vs 1500 m
Taxa Richness

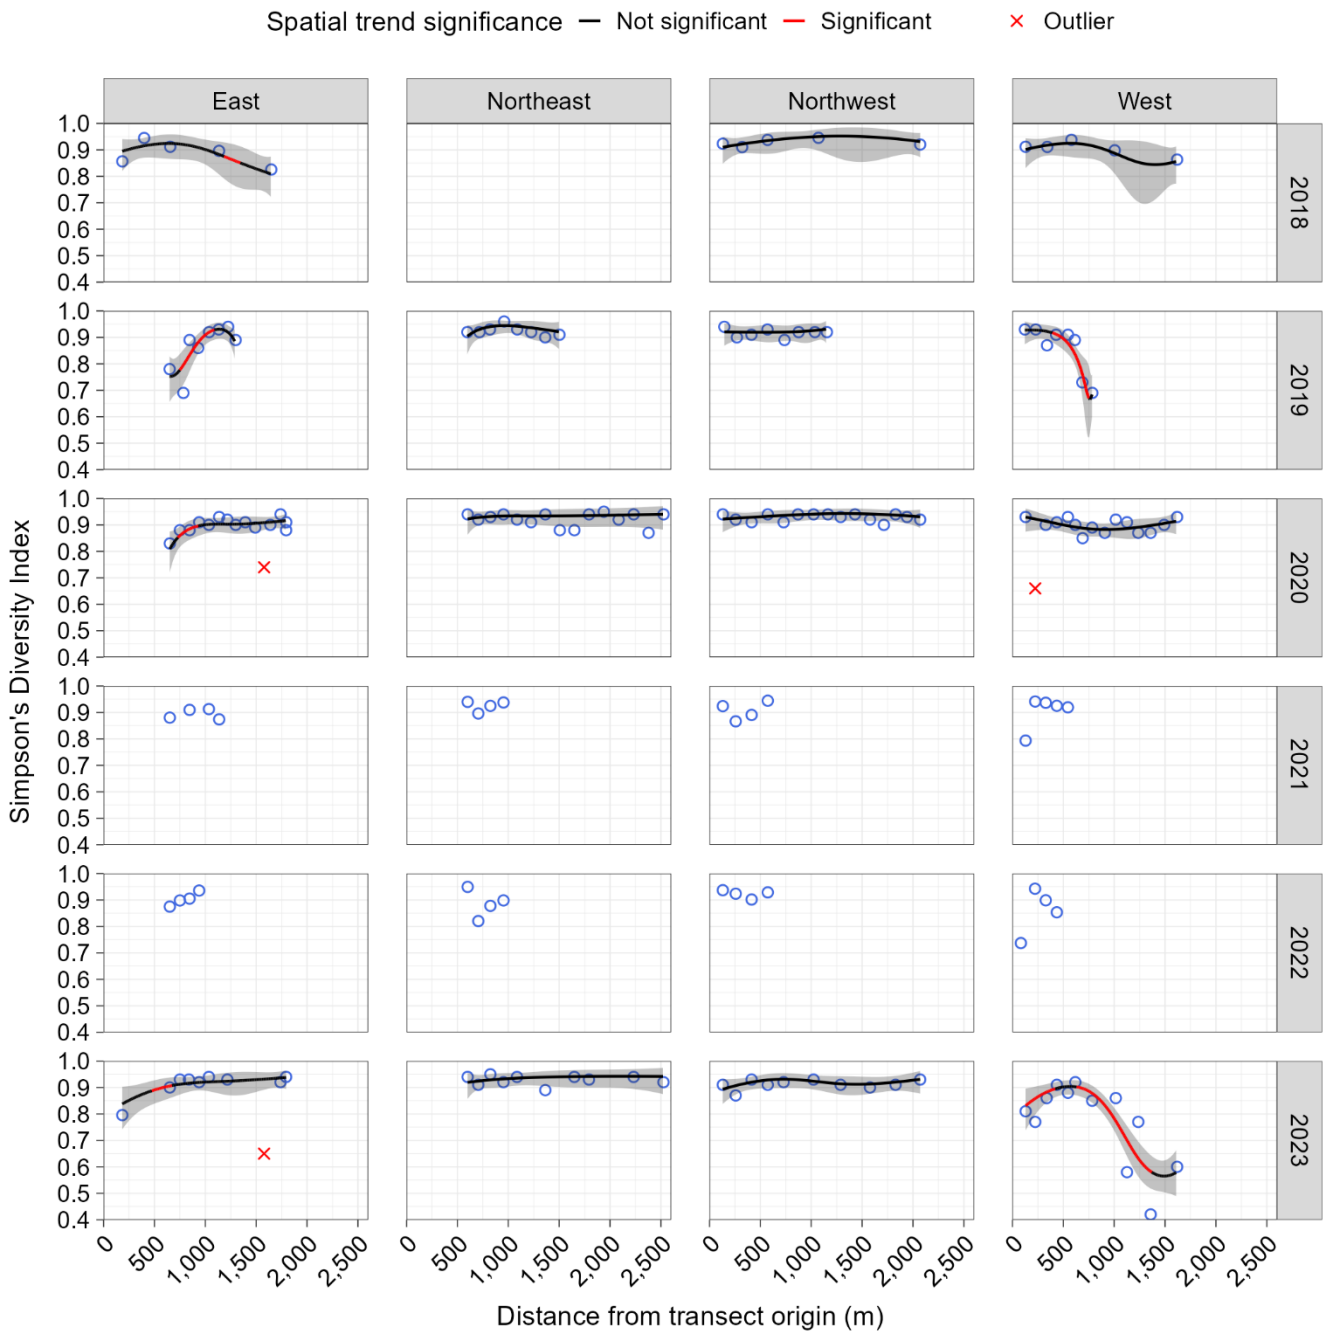
Notes: Values are shown as: P-value (Effect Size, %). Cells highlighted **blue** indicate statistically significant results for comparisons to 2023 (p-value <0.05), while **bold** values indicated statistically significant results between previous monitoring years. Positive effect sizes indicate richness is higher in the past. Negative effect sizes indicate richness is higher in the more recent year.
- = Data not available for comparison.

4.4.3.3 Simpson's Diversity Index

The Simpson's Diversity Index (SDI) three-way interaction between distance, transect, and year was statistically significant (Table 4-2), indicating interannual differences in the relationship between SDI and distance along different transects. Percent fines was also a statistically significant explanatory variable of benthic infauna richness (Table 4-2).



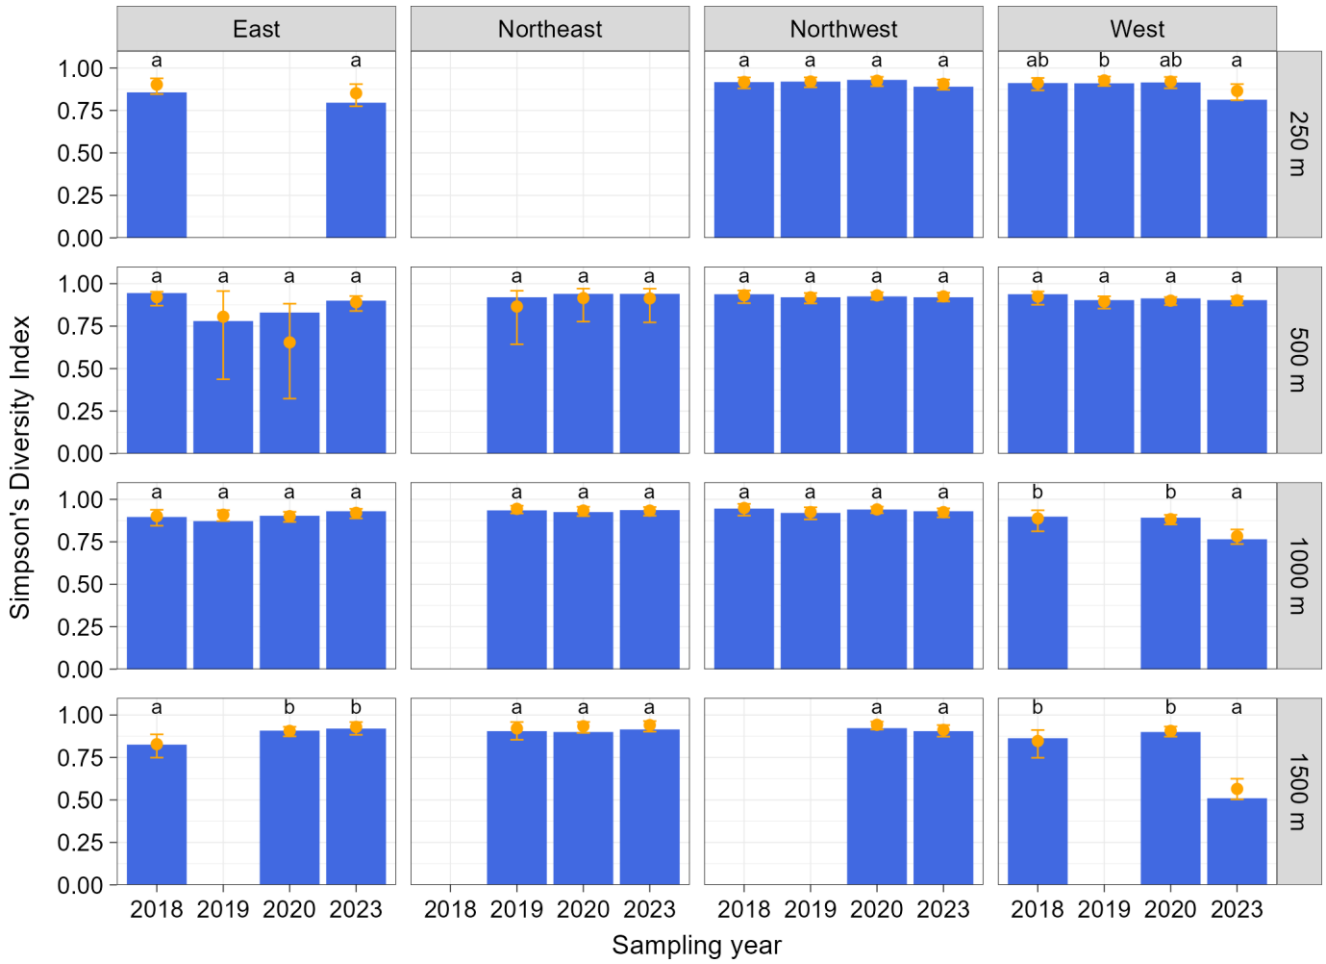
SDI had a non-linear relationship with distance from the Ore Dock area along the East and West transects in all sampling years, along the Northeast transect in 2019, and along the Northwest transect in 2023 (Figure 4-15). SDI showed a general increase with distance from the Ore Dock area along the East Transect, peaking at ~1,500 m in 2020 and 2023 (Figure 4-15). Significant differences within transects in a given year were only identified for 2023 on the West Transect (Figure 4-15; Table 4-7). SDI along the West Transect peaked ~500 m in 2023 then significantly decreased to a low at 1,500 m (Figure 4-15; Table 4-7).

Significant differences between 2023 and previous years were identified only along the East and West transects (Figure 4-16; Table 4-8), as follows:

- **East Transect**—SDI did not vary significantly between years, except at a distance of 1,500 m where 2020 and 2023 SDI values were significantly greater than 2018 (Figure 4-16; Table 4-8).

- **West Transect**—SDI was significantly lower in 2023 compared to 2019 at 250 m from the Ore Dock area (Table 4-8). Diversity was also significantly lower at 1,000 m and 1,500 m in 2023 compared to 2018 and 2020 (Figure 4-16; Table 4-8).

Statistical power was sufficient to detect a reduction of 57–72% in SDI along each transect between 1,000 m from transect origin and the first sampling station, or an increase of +177% at the West Transect (Appendix 4E). Only one observed difference was larger than these effect size cutoffs, with an increase of 362% in SDI at the West Transect. For the temporal effects, statistical power was sufficient to detect decreases in SDI ranging between -65% and -44% for three of the transects or an increase ranging between 82% and 110% for the Northwest and West transects (Appendix 4E). Power to detect increases in SDI was generally low, since observed SDI values were generally high, and due to the bounding of SDI between 0 and 1, further increases in SDI would be difficult to detect.



Measured Simpson's Diversity index (open circles) and mean SDI (lines) plus 95% confidence intervals (grey ribbons) are shown for each sampling year and transect. Red lines indicate a significant spatial trend (p-value <0.05), black lines indicate no significant trend. No data were collected in 2019 along the Northwest Transect at farther distances, precluding comparisons to 2018, 2020, and 2023. Data collected in 2021 and 2022 (n = 17 and n = 16, respectively) were part of the Aquatic Invasive Species (AIS) surveys, not part of the radial study design, and are included for completeness.

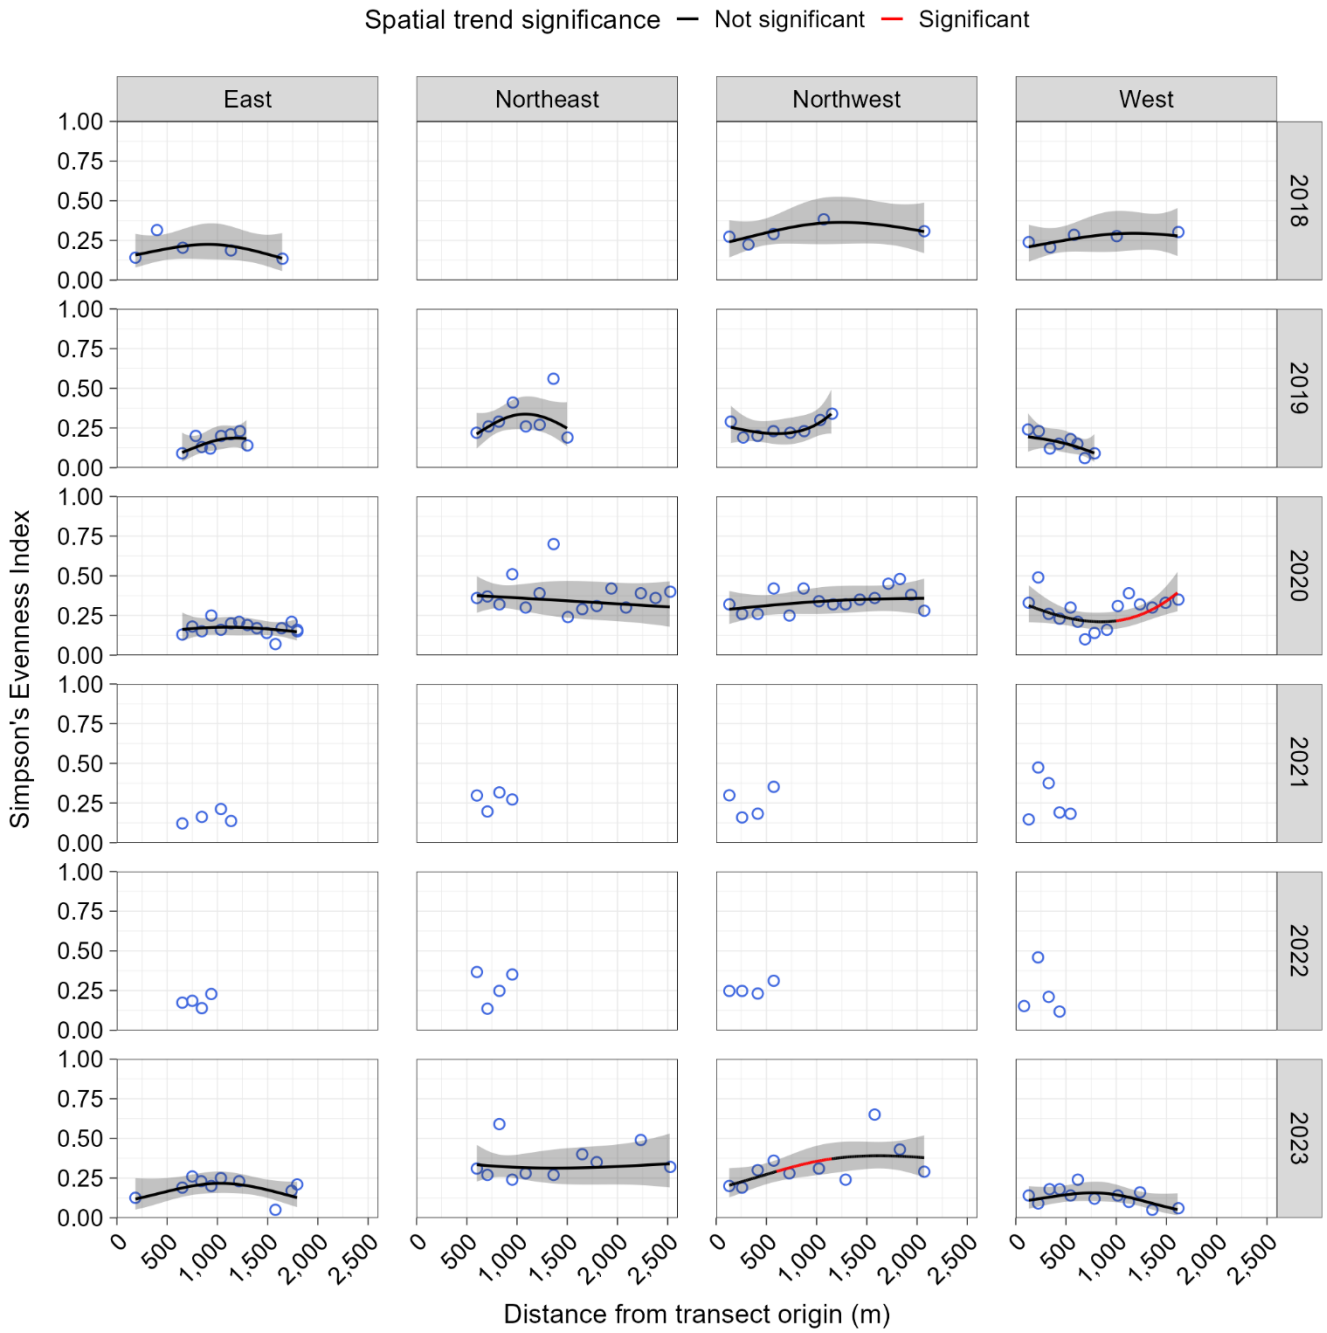
Positive effect sizes indicate SDI is higher in the past. Negative effect sizes indicate SDI is higher in the more recent year.
- = Data not available for comparison.



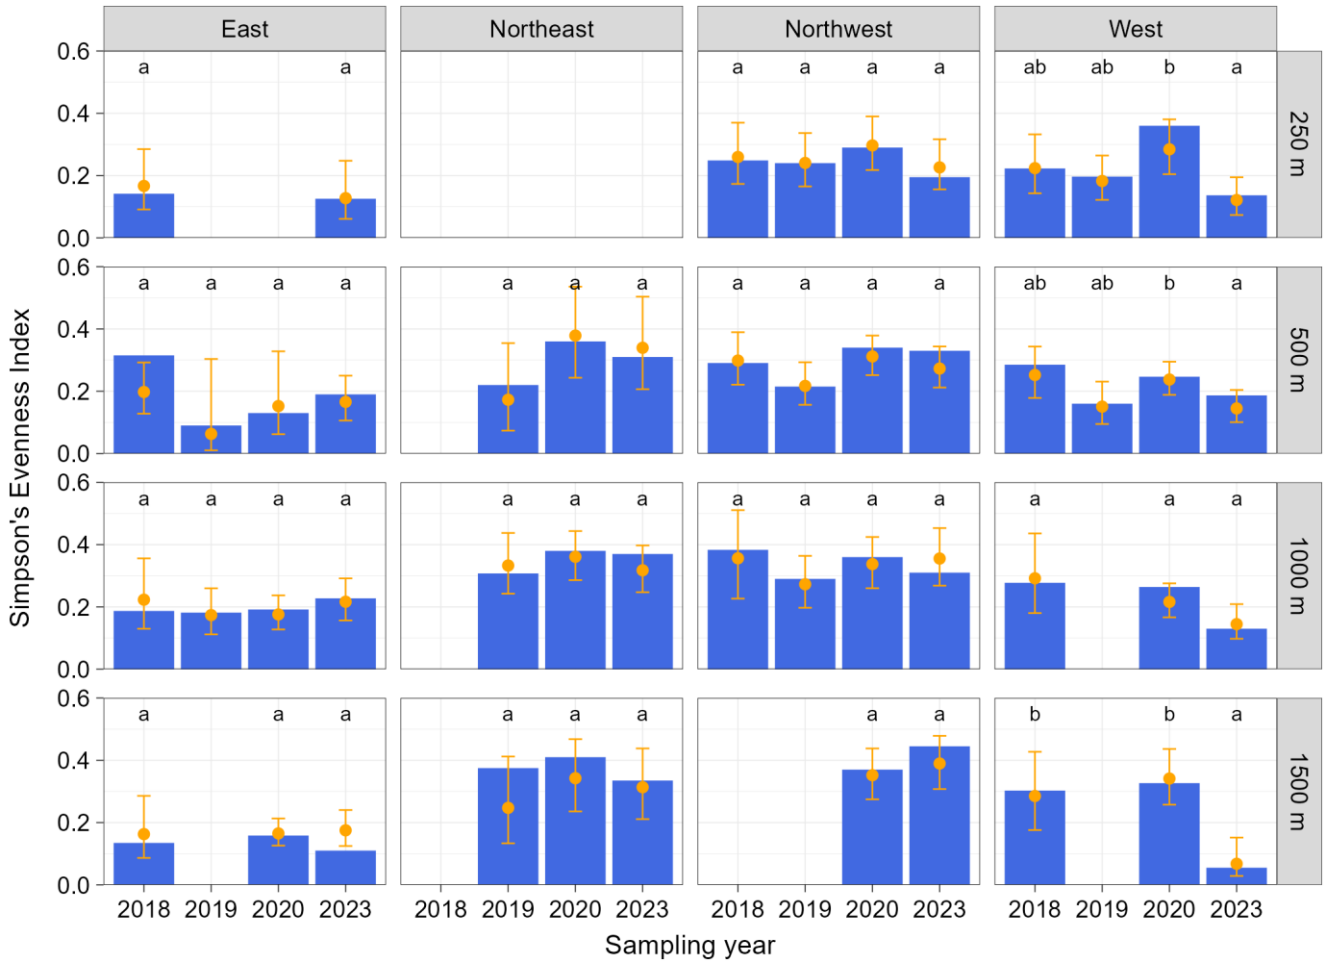
4.4.3.4 Simpson's Evenness Index

The Simpson's Evenness Index (SEI) three-way interaction between distance, transect, and year was not statistically significant, and no two-way interactions were significant (Table 4-2). The main effects of distance from Ore Dock area, year, and transect were significant, indicating significant differences in SEI between distances along the transects, the sampling years, and the transects (Table 4-2). Percent fines was not a statistically significant explanatory variable of benthic infauna SEI (Table 4-2).

Spatial trends in SEI were not consistent between years along the East and Northeast transects, with several years where little variation in SEI values over distance (i.e., no spatial trend present). In contrast, SEI generally increased with distance along the Northwest Transect and showed significant, non-linear trend with distance along the West Transect (Figure 4-17). In 2023, SEI was relatively consistent with distance, except for the Northwest Transect, which showed significant increases in SEI with increasing distance from the Ore Dock area (Figure 4-17).

Significant differences between 2023 and previous years were identified only along the West Transect (Figure 4-18; Table 4-10). At 250 m and 500 m, SEI was significantly lower in 2023 compared to 2020. In addition, at 1,500 m SEI in 2023 was significantly lower than 2018 and 2020. No other significant differences were observed (Table 4-10).

Statistical power was sufficient to detect a reduction of 69–92% in SEI along three of the four transects between 1,000 m from transect origin and the first sampling station, or an increase of 175-390%, depending on the transect (Appendix 4E). None of the observed effect sizes had sufficient statistical power. For the temporal effects, statistical power was sufficient to detect decreases in SEI ranging between -55% and -75% for three of the transects or an increase at effect sizes ranging between 90% and 170% for three of the transects (Appendix 4E). The large effect sizes required to obtain sufficient power for increasing SEI were due to the low SEI values used as the baseline (e.g., the SEI values at the end of the transect). This was especially noticeable for the West Transect, where the 2023 SEI value at the end of the transect was only 0.06, leading to an effect size of +390% required for sufficient power.



Measured Simpson's Evenness index (open circles) and mean SEI (lines) plus 95% confidence intervals (grey ribbons) are shown for each sampling year and transect. Red lines indicate a significant spatial trend (p-value <0.05), black lines indicate no significant trend. No data were collected in 2019 along the Northwest Transect at farther distances, precluding comparisons to 2018, 2020, and 2023. Data collected in 2022 (n = 16) were part of the Aquatic Invasive Species (AIS) surveys, not part of the radial study design, and are included for completeness.

4.4.4 Capesize Vessel Existing Conditions Sampling Program

Benthic invertebrate community samples were collected from eight stations located in close proximity to the Ore Dock at Milne Port to characterize existing conditions prior to the use of the larger Capesize vessels within the study area in fall 2023 (Figure 4-1). These stations included five from existing transects (SNW-1, SW-1, SW-2, SW-3, and SW-4) as well as two newly added stations (SCV-1 and SCV-2) and one station previously used only for sediment quality (SE18-1). Sampling of Capesize vessel stations was completed by 19 August 2023, and the first Capesize vessels arrived in the area on 29 August, 2023.

Benthic invertebrate community indicators calculated from infaunal data collected at the eight stations are summarized in Figure 4-19 and described below.

- **Total Density**—Density was comparable between stations except for stations SW-2 and SW-4 in the West Transect. The lowest observed density was at station SW-3, which lies in between the two highest observed densities, so density was highly variable in this section of the West Transect. The density range observed in the Capesize stations was within the overall range of densities seen along benthic transects.
- **Richness**— Richness was highest at station SW-4 and lowest at SW-1. As with density, the greatest variation in richness was observed between West Transect stations closer to the Ore Dock area, but

richness at the Capesize stations were within the range of richness values documented for the four radial transects in the 2023 program (Figure 4-19).

- **Simpson's Diversity Index**—All stations had diverse communities, with SDI values ranging from 0.77 to 0.93, which were highest at the newly-introduced stations SCV-1 and SCV-2. However, all Capesize stations had similar diversity to stations along the East and West transects (Figure 4-19).
- **Simpson's Evenness Index**—SEI was highest at station SCV-2 and lowest at SW-2 compared to other stations, but was generally low, ranging from 0.09 to 0.30 overall. This indicates that distribution of organisms across taxa was generally uneven, and that a few taxa made up the majority of organisms in the community. These values were comparable to other nearby stations (Figure 4-19).

4.4.5 TARP Assessment

Results of the benthic infauna assessment above were screened against the TARP criteria (Table 4-2). The 'Low Risk' threshold was not triggered in 2023 because the spatial and temporal trend analysis for density and taxa richness did not suggest a pattern indicative of Port-related effects beyond FEIS predictions, and the low risk status/threshold was not triggered for benthic infauna.

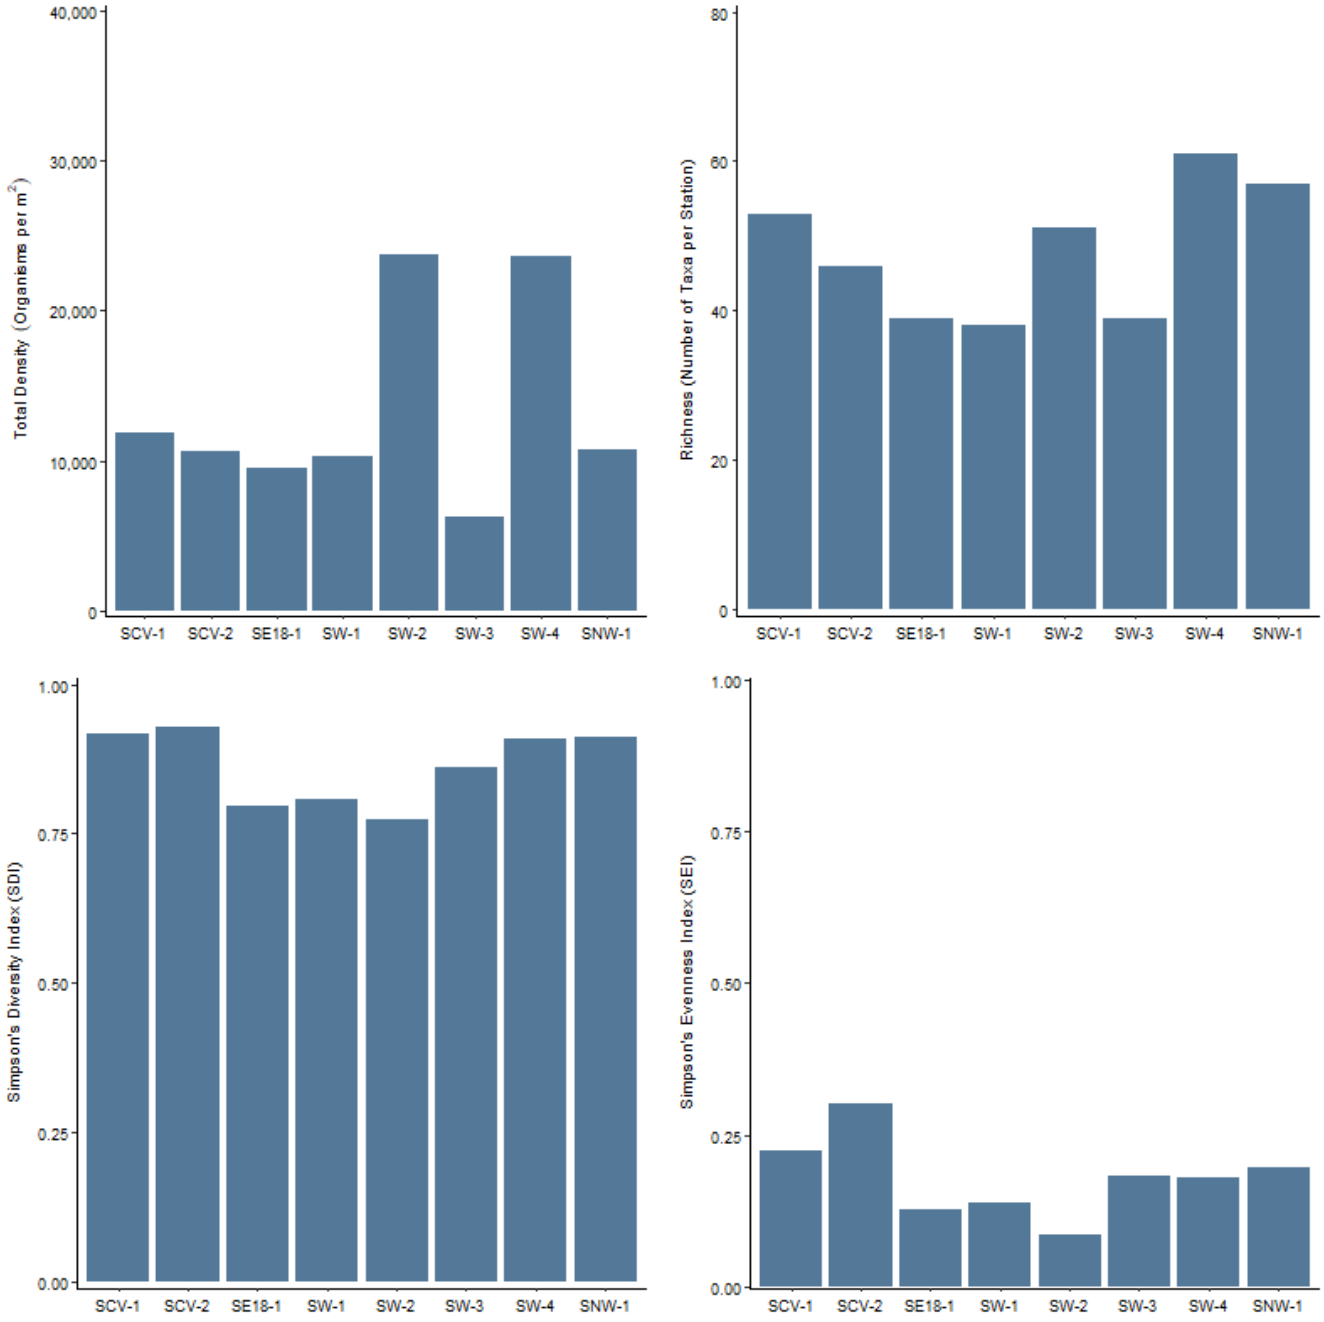

Figure 4-19: Community Endpoints of Benthic Infauna from Capesize Vessel Stations Near the Ore Dock Area, Milne Port, 2023.

4.5 Discussion

Over four monitoring years, the MEEMP has characterized the benthic infaunal community along both coastal and offshore transects radiating out from the Ore Dock area. As discussed below, the 2023 MEEMP provided a characterization of benthic infauna along two coastal and two offshore transects, as well as sampling of several stations closer to the Ore Dock area to provide benthic infaunal community data for existing conditions prior to the use of larger ore carriers (Baby Cape and Capesize) at Milne Port[3].

In 2023, benthic infaunal communities along the offshore and coastal transects were largely dominated primarily by polychaetes, followed by Malacostraca, then ostracods and bivalves. While richness, diversity, and evenness were within comparable ranges for the four transects, benthic invertebrate densities were greater and more variable along the coastal transects compared to the offshore transects. The observed difference in invertebrate densities between the coastal and offshore transects are expected and reflect the natural variation in substrate characteristics between nearshore and offshore habitats, as described in Section 3.0. The proportion of fine-grained sediments increased with greater distance from the shore due to internal mixing and sediment redistribution processes, such that finer sediments tended to accumulate further from shore. Closer to shore at shallower depths, substrates were more variable due to the influence of the nearshore environment and features such as Phillips Creek. Within the shallower coastal environment, benthic densities were naturally higher in sheltered areas characterized by finer sediments but were lower in more exposed areas with sandier substrates. Variability within the coastal transects is likely due to natural variability in substrate type, in addition to the influence of the Phillips Creek inflow, through localized changes in substrate type, hydrology, and water quality (e.g., total suspended solids, salinity).

Marine benthic infaunal communities are influenced by abiotic factors, such as sediment grain size, organic carbon concentration, depth, inundation time, and salinity (Eckman 1996; Ricciardi and Bourget 1999; Hyland et al. 2005). When comparing nearshore and offshore habitats, water depth becomes an important consideration as the density and biomass of marine benthic infauna generally decreases with increasing water depth and distance from land (Wei et al. 2010; Degen et al. 2015). The driving force behind this pattern is the decrease in food input, depending on the regionally varying surface production and the assimilation efficiency in the water column (Gage and Tyler 1991; Levin et al. 2003). Productivity (and hence food) tends to be higher in shallower, nearshore habitats, primarily due to increased light penetration through the water column to the bottom sediments, and warmer ambient water temperatures. In deeper waters, such as those along the Northern Offshore transects, decreased light penetration and colder water temperatures naturally limit benthic habitat productivity. At comparable depths, sediment grain size is likely the single best predictor of benthic invertebrate community characteristics (Ricciardi and Bourget 1999). In general, smaller sediment grain sizes correspond to higher invertebrate abundance, biomass, and diversity (Heck et al. 1995; Sewell 1996) because of the larger available surface area for adhesion of organic particles (i.e., total organic carbon [TOC]), which constitute an important food source for invertebrates. Habitats with finer sediment therefore tend to be naturally more productive and support more abundant communities.

[3] The eight Capesize vessel stations were sampled from August 4-19, 2023 and the first Capesize vessel arrived in Milne Port on 29 August 2023.

4.5.1 Statistical Comparisons of Community Indicators

Total density, richness, and diversity were significantly higher at stations closer to the Ore Dock area along the West Transect in 2023, which is not indicative of adverse effects on the benthic communities from Port activities at or close to the Ore Dock area, even though sediments appear to have been locally impacted by scouring due to propeller wash as predicted by the FEIS. Comparison of diversity in the West Transect across years indicates that overall diversity near the Ore Dock area in 2023 was comparable to those observed in 2018 and 2020.

In 2023, benthic infaunal communities were diverse throughout the study area and well established in both habitat types. There were no consistent differences (i.e., trends, or directional change) between years in benthic community indicators along each of the four transects. Also, statistical differences tended to occur with greater distance from the Ore Dock area rather than closer to the dock. These results do not align with the community response pattern typical of a toxicological impairment due to contaminant exposure (i.e., a significant decrease in both density and richness). If both these indicators were to show a pattern of being significantly reduced, then the community could become increasingly simplified as contaminant-sensitive taxa disappear or numbers are diminished, leaving more tolerant taxa to dominate the community (Environment Canada 2012). However, the 2023 results are more consistent with expected natural variability for these benthic habitat types within Milne Inlet and there is no evidence to suggest that benthic infaunal communities have been affected by the Project. A lack of adverse effects on local benthic communities that can be linked to the Project is consistent with FEIS predictions of no significant adverse residual effects to Arctic Char habitat. In 2023, mitigation measures appeared to be functioning as intended and Project operational activities were being managed in a way that did not adversely affect benthic infauna at Milne Port.

4.5.2 Potential Effects of Propeller Wash and Scouring in West Transect

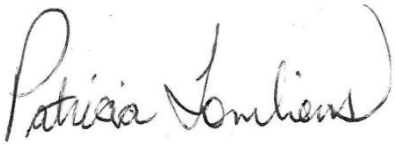
There was a decreasing trend in the West Transect with distance from the Ore Dock area for total density and richness in 2023, a nonlinear relationship for diversity, and no trend in evenness. Community indicators at West Transect stations were variable between 2019 and 2023, with a notable decline in density, richness, diversity, and evenness at station SW-2 in 2020. This appears to have been driven by a change in grain size in 2020, and data from subsequent years indicate that the community at SW-2 has since recovered from this decline. Total density at station SW-2 was higher than all other West Transect stations, and richness was high, and similar to other stations. There was some decrease of richness, diversity, and evenness at the adjacent station SW-1 in 2022 which, again, coincided with a drop in percent fines of the sediment. The effects were less substantial than those observed in 2020 at SW-2, and were not accompanied by a decrease in total density. Community indicators at SW-1 also appear to have recovered in 2023, consistent with FEIS predictions of minor sediment disturbances which stabilize over time. The differences observed between years may also reflect a degree of natural variability.

4.5.3 Sediment Sampling to Support Assessment of the Use of Capesize Vessels

Eight stations (SW-1 through SW-4, SCV-1, SCV-2, SE18-1, and SNW-1) were sampled in 2023 as part of the Capesize Vessel Existing Conditions Sampling Program to establish baseline conditions prior to the arrival of Baby Cape and Capesize ore carriers in Milne Inlet. Consistent with the Northern and Coastal transect stations, benthic communities showed some variability in benthic indicators. Results for these stations appear to be consistent with overall MEEMP project stations.

4.6 Conclusions and Recommendations

The results of the 2023 MEEMP, combined with previous years of monitoring, indicate that the Project has not caused adverse impacts on benthic infauna at Milne Port. This conclusion is supported by similar or elevated density and richness at stations nearest to the Ore Dock area and relatively few changes to overall community composition across transects. There was evidence of potential propeller wash at one station (SW-2) in 2020, which prompted follow up programs with targeted sampling in 2021 and 2022 before a return to scheduled sampling in 2023. Data collected from 2021 through 2023 generally indicate that the benthic community at that station have since recovered, and that the effects were temporary and localized.



The benthic infauna results, in combination with those from sediment monitoring to date, suggest that mitigation measures are functioning as intended and that Project activities are being managed in a way that has not adversely affected benthic infaunal communities within the Milne Inlet study area. Given that there will be continued use of larger ore carriers (Baby Cape and Capesize) at Milne Port, Baffinland has committed to a frequency of annual sampling of the newly implemented Capesize monitoring stations, for a minimum of three years (2023 to 2025) to identify Project-related effects due to the change in vessel types.

4.7 Closure

We trust this information is sufficient for your needs at this time. Should you have any questions or concerns, please do not hesitate to contact Phil Rouget, on behalf of the undersigned, at +1 250 419 4945.

Biologica Environmental Services Ltd. Methods

Marine Benthic Enumeration and Identification Methods
Client: WSP
Project: Baffinland MEEMP
Protocol: EEM

Sample Inventory

Sample arrival: 7-Sep-23
Number of samples: 44
Number of jars: 67
Screen size: 500 µm and 1.0 cm
Biologica project number: mb23-059

The chain of custody documents were checked and approved with the client. Samples were transferred from formalin into 70% ethanol and stained with Rose Bengal to aid in sorting. Each sample was provided a unique identification number and placed in the queue for analysis.

Sample Processing

Sorting and Subsampling:

All samples were sorted using dissecting microscopes at 10–40x magnification by trained personnel. Microscopic sorting is the only way to ensure >90% of organisms are removed from the debris, which is required by EEM (Environment Canada; Environmental Effects Monitoring) guidelines for marine benthic analyses. To minimize potential sorter bias, samples were distributed among technicians such that no one person sorted all the replicates of a given sample.

Due to historically the large volumes and high abundances in the samples, samples were fractioned in the field into a 1.0 cm macro fraction and 500 µm fine fraction. This strategy was developed to maximize the detection of large and rare individuals in the macro fraction while accurately enumerating smaller organisms in the fine fraction. The macro 1.0 cm fraction was analyzed whole, with all large organisms (>1.0 cm) removed from the sample, as was done in previous years for this project. In addition, all large debris in this fraction were checked microscopically, including rocks and other large debris to ensure encrusting organisms were accurately enumerated.

Biologica subsampled the fine 500 µm fraction. The 500 µm fraction was split in the field to 1/4. Biologica subsequently split this fraction by a second 1/4 split, for a final 1/16 split. Subsampling was done with a Caton tray (Caton, 1991). The sample was spread evenly over a Caton grid, and

sequential random quadrats were selected and sorted until the minimum 1/4 lab split was reached.

Sub-sampling accuracy was assessed by sorting the remaining sample for 10% (n= 4) of all sub-sampled samples and comparing the fractions to one another. Refer to Table 2 for sub-sampling accuracy results.

Sorting QA/QC:
To ensure sorting efficiency was >95%, whole and/or partial sub-samples were re-sorted. Sorting efficiency was calculated using the following equation (where total count = final total number of organisms in sample):

Sorting efficiency = [1−(# of organisms in spot check or re-sort / total organisms)] x 100
*Total organisms includes the original count and the number found from the re-sort

All samples checked must meet or exceed 95% sorting efficiency. Any samples falling below 95% sorting efficiency are re-sorted in their entirety, and additional checks are undertaken as necessary. For quality assurance, QA re-sorts were performed on 10% of samples. Four samples were randomly selected and re-sorted in their entirety. Refer to Table 2 for sorting efficiency results.

Table 2. Summary of sorting QA/QC results for WSP Baffinland MEEMP, 2023.

Client Sample ID	Biologica Sample ID	Sorting Efficiency QA Whole Re-sorts	Sub-sampling accuracy
SCV-2	mb23-059-114	99.05%	
SE-4	mb23-059-118		74.21%
SNE-1	mb23-059-125	95.37%	
SNW-1	mb23-059-135		66.88%
SW-3	mb23-059-147	96.43%	
SW-4	mb23-059-148		76.36%
SW-12	mb23-059-154	97.99%	
SW-15	mb23-059-156		77.98%
	Average:	**97.12%**	**73.86%**

Identification and Invasive Species Detection:

All organisms were identified using a combination of dissecting (10–40x) and compound microscopes (100–1000x) and standard taxonomic keys (see methodological and taxonomic references) to the lowest practicable level (species whenever possible). All specimens were archived in air-tight glass vials with glycerin and 70% ethanol for long-term storage. Taxonomic data were recorded in Biologica's custom database.

During the identification process, taxonomists recorded if any identified taxa were beyond their recorded range and/or potentially introduced (originating from another location) or invasive (both introduced and appearing to proliferate with possible detrimental effects to the ecosystem and/or industry). One genus of interest over the past several years of sampling has been *Marenzelleria.* Multiple specimens were externally verified by DNA analysis by Dr. Vasily

Radashevsky from the National Scientific Center of Marine Biology and were confirmed to be *Marenzelleria wireni*. Historical identifications can all be taken to this species identification. **No taxa observed were identified as putative invasive taxa**.

Twelve new taxa to the project were identified, of which will be sent for verification. There were also a few levels of identification that were new to the project, however all these identifications have been present at a lower level (genus/species) in the past.

Reference Collection:

Biologica houses a reference collection of all taxa that have been observed in the Baffinland MEEMP project thus far. Taxa are added to this reference collection yearly. These may be new taxa and/or new stages. Taxa new to the project are sent for external verification. This collection consists of a minimum of one specimen representing each taxon and stage, with five specimens per taxon/stage wherever possible. These specimens were labelled, given a location code, and placed in evaporation-resistant shell dram vials. Approximately 1 mL of glycerin was added to each vial to prevent desiccation.

Data Management and Analysis

All data were recorded in Biologica's custom database. Total abundances were extrapolated for samples split in the field and the lab to represent the abundance from the whole sample. Organism densities were calculated by dividing the total organism abundance (extrapolated if the sample was split) using the area of a Van Veen grab (0.1 m^2), with three composite Van Veen grabs (3 x 0.1m^2) for each sample.

Results were provided to the WSP project manager in Excel spreadsheets via email.

APPENDIX 4C

Biologica Environmental Services Ltd. Raw Data

Abbreviations & Definitions

Worksheets:

1. Abbreviations & Definitions	Glossary of terms and outline of report.
2. Data-Matrix	Total abundance data in matrix format, including total taxa count per sample and total abundance per sample.
3. Data-Long	Raw abundance data in long format.
4. QC-QA Report	Results of sorting efficiency.
5. Subsampling Accuracy	Raw subsampling accuracy data based on preliminary abundance counts.
6. Provisional Taxa	Description of unique taxa that are undescribed and assigned internal numbers (e.g., sp. 1, sp.2 etc.)
7. Taxaonomic Updates	Taxonomic updates for historical data considerations and verification purposes.

Life Stages:

A	Adult
Int	Intermediate - has adult features but not of typical reproductive size
J	Juvenile
L	Larvae
N	Nymph
P	Pupa
Col	Colony
Deut	Deutonymph
MEMO	Incidental taxa/fragments not included in data, or whose abundance is not generally captured accurately by 1.0mm screen.
MEIO	Meiofauna
Total Number of Taxa	Number of unique taxa (=species richness), not including higher-order taxa for which there exists a lower-order identification (e.g. not including *Lumbrineris* sp. if there exists *Lumbrineris cruzensis* in the data).
Total Number of Organisms	Total Abundance, not including incidental taxa
URL	Unique, rare, large (>1.0 cm) taxa removed from the whole sample
BDL	Below detection limit. Used for biomass measurements for weights less than 0.00001g.

Biologica Coding

Major Taxonomic Groups:

Taxa Group	Group Code	Taxonomic Group
Annelida	ANHI	Annelida Hirudinea
Annelida	ANOL	Annelida Oligochaeta
Annelida	ANXX	Annelida
Annelida	POER	Polychaeta Errantia
Annelida	POSE	Polychaeta Sedentaria
Annelida	POXX	Polychaeta
Arthropoda	CHAR	Chelicerata Arachnida (Acari)
Arthropoda	CHPY	Chelicerata Pycnogonida
Arthropoda	CHXX	Chelicerata
Arthropoda	CRAM	Crustacea Amphipoda
Arthropoda	CRCI	Crustacea Cirripedia
Arthropoda	CRCL	Crustacea Cladocera
Arthropoda	CRCO	Crustacea Copepoda
Arthropoda	CRCU	Crustacea Cumacea
Arthropoda	CRDE	Crustacea Decapoda
Arthropoda	CRDI	Crustacea Diplostraca
Arthropoda	CREU	Crustacea Euphausiacea
Arthropoda	CRIS	Crustacea Isopoda
Arthropoda	CRLE	Crustacea Leptostraca
Arthropoda	CRMY	Crustacea Mysidacea
Arthropoda	CROS	Crustacea Ostracoda
Arthropoda	CRTA	Crustacea Tanaidacea
Arthropoda	CRXX	Crustacea
Arthropoda	INCM	Insecta Collembola
Arthropoda	INCO	Insecta Coleoptera
Arthropoda	INDI	Insecta Diptera
Arthropoda	INEP	Insecta Ephemeroptera
Arthropoda	INHM	Insecta Hemiptera
Arthropoda	INHY	Insecta Hymenoptera
Arthropoda	INLE	Insecta Lepidoptera
Arthropoda	INMG	Insecta Megaloptera
Arthropoda	INNE	Insecta Neuroptera
Arthropoda	INOD	Insecta Odonata
Arthropoda	INPL	Insecta Plecoptera
Arthropoda	INTH	Insecta Thysanoptera
Arthropoda	INTR	Insecta Tricoptera
Arthropoda	INXX	Insecta
Arthropoda	MYCH	Chilopoda
Arthropoda	MYDI	Diplopoda
Echinodermata	ECAS	Echinodermata Asteroidea
Echinodermata	ECCR	Echinodermata Crinoidea
Echinodermata	ECEC	Echinodermata Echinoidea
Echinodermata	ECHO	Echinodermata Holothuroidea
Echinodermata	ECOP	Echinodermata Ophiuroidea
Miscellaneous	ACAN	Acanthocephala
Miscellaneous	AMPH	Amphibia
Miscellaneous	BRAC	Brachiopoda
Miscellaneous	BRYO	Bryozoa
Miscellaneous	CHAE	Chaetognatha
Miscellaneous	CILI	Ciliophora Ciliophora
Miscellaneous	CNAN	Cnidaria Anthozoa
Miscellaneous	CNHY	Cnidaria Hydrozoa
Miscellaneous	CNSC	Cnidaria Scyphozoa
Miscellaneous	CNXX	Cnidaria
Miscellaneous	CTEN	Ctenophora
Miscellaneous	ENTO	Entoprocta
Miscellaneous	EURA	Echiura
Miscellaneous	FORA	Foraminifera
Miscellaneous	HEMI	Hemichordata
Miscellaneous	KINO	Kinorhyncha
Miscellaneous	NODA	Nemata
Miscellaneous	NTEA	Nemertea
Miscellaneous	PHOR	Phoronida
Miscellaneous	PIXX	Pisces
Miscellaneous	PLTY	Platyhelminthes
Miscellaneous	PORI	Porifera
Miscellaneous	PRIA	Priapulida
Miscellaneous	ROTI	Rotifera
Miscellaneous	SIPN	Sipuncula
Miscellaneous	TARD	Tardigrada
Miscellaneous	URAP	Appendicularia
Miscellaneous	URAS	Ascidiacea
Miscellaneous	URTH	Thaliacea
Mollusca	MOAP	Mollusca Aplacophora
Mollusca	MOBI	Mollusca Bivalvia
Mollusca	MOCE	Mollusca Cephalopoda
Mollusca	MOGA	Mollusca Gastropoda
Mollusca	MOPO	Mollusca Polyplacophora
Mollusca	MOSC	Mollusca Scaphopoda
Mollusca	MOXX	Mollusca

biologica

Description of unique taxa that are undescribed and assigned internal numbers (e.g., sp. 1, sp. 2 etc.) for WSP Baffinland MEEMP, 2023.

taxcode	grpcode	TaxonName	Morphological Description	Note
ANNE	POSE	Dialychone sp. 1	Methyl Green staining pattern is similar to Paradialychone harrisae observed in California, but has ventral cleft present on collar which is lacking in California specimens.	Present in 2022
ANNE	POSE	Dialychone sp. 2	There is a well-defined circular unstained area in the middle of the ventral collar. There is no ventral cleft present. Likely not described.	Present historically
ANNE	POSE	Dialychone sp. 3	Similar to Chone duneri, with a simple depression on posterior. Thoracic chaetae with long macron, prostomium not covered, with oval shaped unstained area on collar. Posterior segments with a reddish brown pigmentation in a striped pattern.	Present historically
ANNE	POSE	Sabellidae sp. 2	Specimens do not have companion chaetae. Eyespots present from setiger 4. Collar similar to Parasabella pallida.	Present historically
ANNE	POSE	Sabellidae sp. 3	cf Chone, but has only capillary setae on the thorax. There is a semicircular unstained section on the collar (Methyl Green). Does not appear to be described in literature.	Present in 2022
ANNE	POSE	Sabellidae sp. 4	Specimens with rectangular staining pattern on the ventral collar. Thorax has long handled setae, with no white glandular ring, ventral cleft present, and a lateral and dorsal incision on collar.	Present historically
ANNE	POSE	Euchone sp. 1	Staining pattern on abdominal segments similar to Euchone analis and with a rectangular glandular area on each side and on the anterior and posterior portion of each segment. Both dorsal and ventral sides of the collar have a large divergent lobe, and there is narrow white glandular area beneath collar on the ventral side.	Present historically

Taxonomic updates for historical data considerations and verification purposes for WSP Baffinland MEEMP, 2023.

Year	Taxon	Biologica Comment	Referenced specimens

APPENDIX 4E

Power Analysis

POWER ANALYSIS - METHODS

A Type I error is concluding there is a significant effect when none exists (i.e., a false positive). Alpha (α) is the probability of committing a Type I error. A Type II error is the probability of concluding there is no significant effect when there is a real effect of some specified magnitude (i.e., a false negative). Beta (β) is the probability of committing a Type II error. The power of a statistical test (1 - β) is the probability of detecting a real effect. In this analysis, the Type I error-rate (α), also referred to as the significance level, was set to 0.05. The desired minimum statistical power was 80%, which corresponds to a type II error-rate of 0.2. Power analyses were conducted to assess the power of statistical tests under multiple effect sizes. For each model, a set of effect sizes was created, based on preliminary power analyses, so that power >80% was achieved at the largest absolute values of effect sizes, but also so that power is assessed at a range of effect sizes. Both negative and positive effect sizes were used, to assess the power of detecting either a reduction or an increase in values of the response variables. Since the analysis focused on assessment of changes to statistical power at different effect sizes, the power analysis used the observed samples sizes from the collected data.

Data Simulation following Effect Size Application

The power to detect statistically significant effects was estimated using residual bootstrapping in R v. 4.3.2 (R 2023), following the approach of Fox and Weisberg (2018). The general approach was to simulate data based on the model selected for interpretation, the observed sample size, and the residuals, and re-run the models that were used for the original analysis using the simulated data. The data simulation and analysis were repeated 5,000 times, and the proportion of repetitions where the *P*-values of interest were significant ($P<0.05$) was interpreted as the statistical power of the test.

To produce simulated data, the original model was used to predict values of the response variable. The predicted values were then adjusted according to the effect size, depending on the analysis (see below for details). The simulated data were then analyzed using the same model structure as the original analysis. Effect sizes and statistical tests were applied differently to different models, as detailed below.

Effect Sizes

In this power analysis, the question of interest was the models' power to detect between-year differences at various distances within transect, as well as the power to detect a significant trend over time along each transect.

To assess the power to detect spatial trends, the effect size was applied linearly, where the first sampling station in each transect had the full effect size, whereas the last sampling station along the transect had an effect size of zero. This simulated the expected distribution, where disturbance was highest in close proximity to the ore dock. The effect sizes were calculated relative to the observed values at maximum distance along each transect, since it was assumed that at the end of each transect, disturbance was minimal. The effect size was only applied to 2023 data, whereas all data collected previously only had an effect size of zero. This allowed assessing what effect size, relative to the values in low-disturbance portion of each transect, the model would be able to identify. The effect size was applied up to a distance of 1,000 m from transect origin, such that at the beginning of the transect, the effect size was applied fully, decreasing linearly with distance until reaching 0% effect size at a distance of 1,000 m. This

distance was selected as a previous assessment of ship wake and propeller wash indicated that sediment scouring and deposition would be limited to less than 1,000 m from the dock (Golder 2018). An example of the effect size application to the Post-2018 Dataset (i.e., 2019, 2020, and 2023) for fines content is provided in Figure 4E-1.

To assess the power to detect between-year differences, the effect size was applied differently than for the effect of distance. Specifically, the effect size was also applied linearly relative to distance from transect origin, and it was also only applied to 2023 data. However, the effect size was calculated relative to the values observed in the previous sampling year (i.e., 2020). This allowed assessing what effect size, relative to the previous sampling year, the model would be able to identify.

The simulated data based on effect sizes applied to values of the response variable from 2023 were combined with simulated data from previous years (with an effect size of zero). This combined dataset was analyzed using the models from the original analysis in the main report.

To estimate the power to detect a spatial effect, the significance of the spatial trend in 2023 was assessed at 500 m and 700 m from transect origin (for Northeast Transect) and at 250 m and 500 m from transect origin (for all other transects) using the package emmeans (Lenth 2019), and the minimum *P*-values for the trend across both distances were retained. The use of two distances per transect allowed the estimation of power to detect at least one significant spatial trend per transect. The proportion of repetitions with *P*-values less than 0.05 was interpreted as the statistical power to detect a spatial effect.

To estimate power to detect a temporal effect, the significance of the difference between 2023 and 2022 was assessed at 500 m from transect origin, and the *P*-value for the comparison was retained. For each effect size, the proportion of repetitions with *P*-values less than 0.05 at each transect was interpreted as the statistical power to detect a year effect. This analysis assessed how much higher or lower the 2023 values would have to be to detect a significant difference relative to the previous sampling year.

Power Analysis – Reporting of Results

Power curves were produced, showing statistical power as a function of effect size in percentages. Horizontal lines were added to visualize statistical power values of 0.8 (hereafter sufficient power) and 0.9 (hereafter high power), and a vertical line was added to visualize the magnitude of difference (or the slope value, for continuous predictor variables) that was observed in the original analysis.

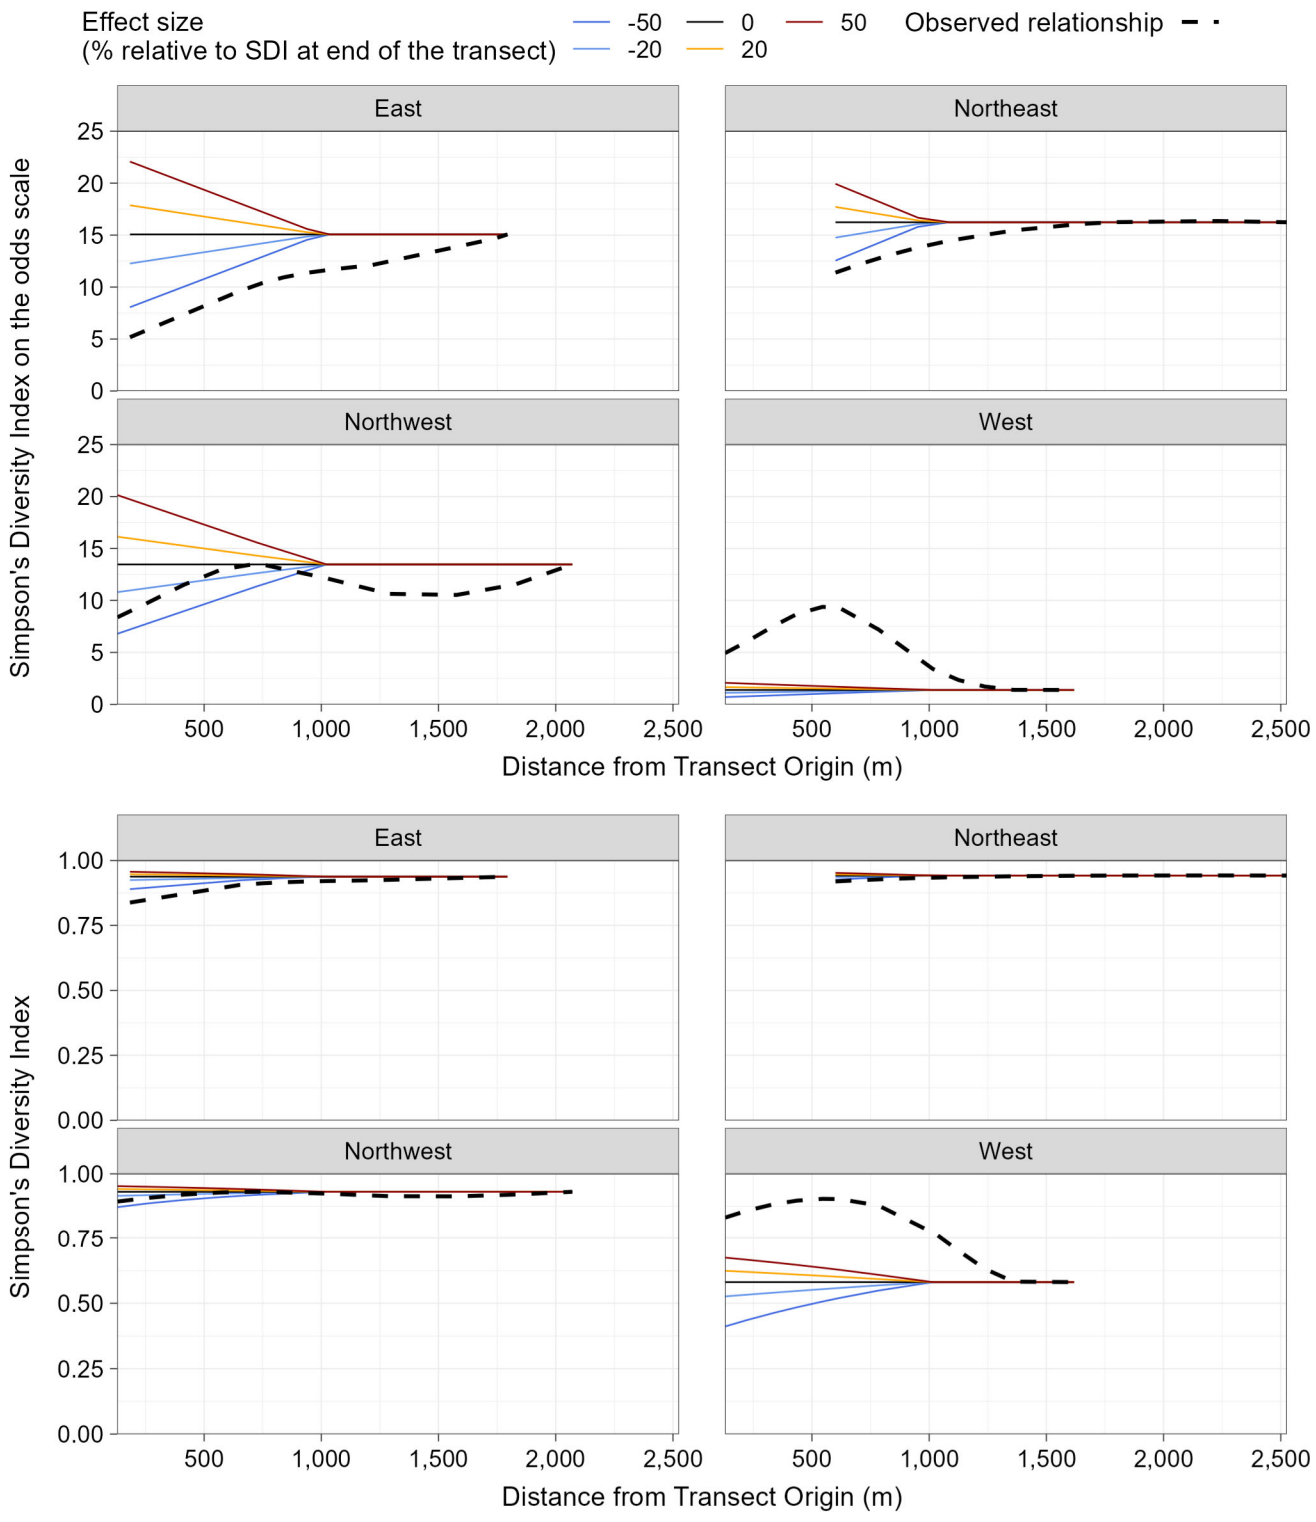

Figure 4E-1: Application of effect sizes to examine effect of distance in SDI, illustrating how effect sizes applied on the odds scale (top) are affected by the bounding of SDI by 0 and 1 once effect sizes are expressed on the SDI scale (bottom).

POWER ANALYSIS – RESULTS

Total Density

The analysis of density had sufficient power (>0.8) to detect spatial effects of decreasing density at effect sizes ranging between -85% (for the Northeast and Northwest transects) and -72% (for the East Transect; Figure 4E-2). Power was also sufficient (>0.8) to detect spatial effects of increasing density at effect sizes ranging between +105% (for the East Transect) and +200% (for the Northwest Transect). Observed effect sizes in 2023 were -42%, +119%, +82%, and +26% for the East, West, Northwest, and Northeast transects, respectively. The model did not have sufficient power to detect any of the observed effect sizes, although it did have power of 0.7 to detect the effect size at the West Transect, consistent with the finding of a significant increasing trend near the transect origin for West Transect in 2023, but not for the remaining transects (Section 4.4.3.1 in the 2023 MEEMP main report [WSP 2024]). The model had higher power to detect decreases in density than increases. Since a reduction in density due to Project activity is of more concern than an increase in density, the statistical power to detect reductions was considered to be more relevant.

For the temporal effects, the model had sufficient power (>0.8) to detect temporal effects of decreasing density at effect sizes of -90% and -67% (Northeast and Northwest transects, respectively), but not at the East Transect; Figure 4E-2). Power was also sufficient (>0.8) to detect temporal effects of increasing density between 2020 and 2023 at effect sizes of ranging between +99% (for the Northwest Transect) and +290% (for the East Transect). Observed effect sizes were +190% and +233% for the East and West transect, respectively, and -9% and +101% for the Northwest and Northeast transects, respectively. Since all substantial observed effect sizes were positive (i.e., increase in density), the low statistical power to detect a decrease in density over time was not considered a concern at this time.

Overall, power to detect decreases in density was higher than power to detect increases. Only one observed temporal effect, and none of the spatial effects, had sufficient power. Of the four transects, three had observed spatial increases in density (i.e., higher density at proximity to the transect origins), and three had substantial increases in density in proximity to transect origin between 2020 and 2023. Power to detect increases in density between 2020 and 2023 in proximity to the transect origins was generally low, since density values observed in 2020 were small, requiring increases of large percent values to detect a significant difference from the simulated 2023 density values.

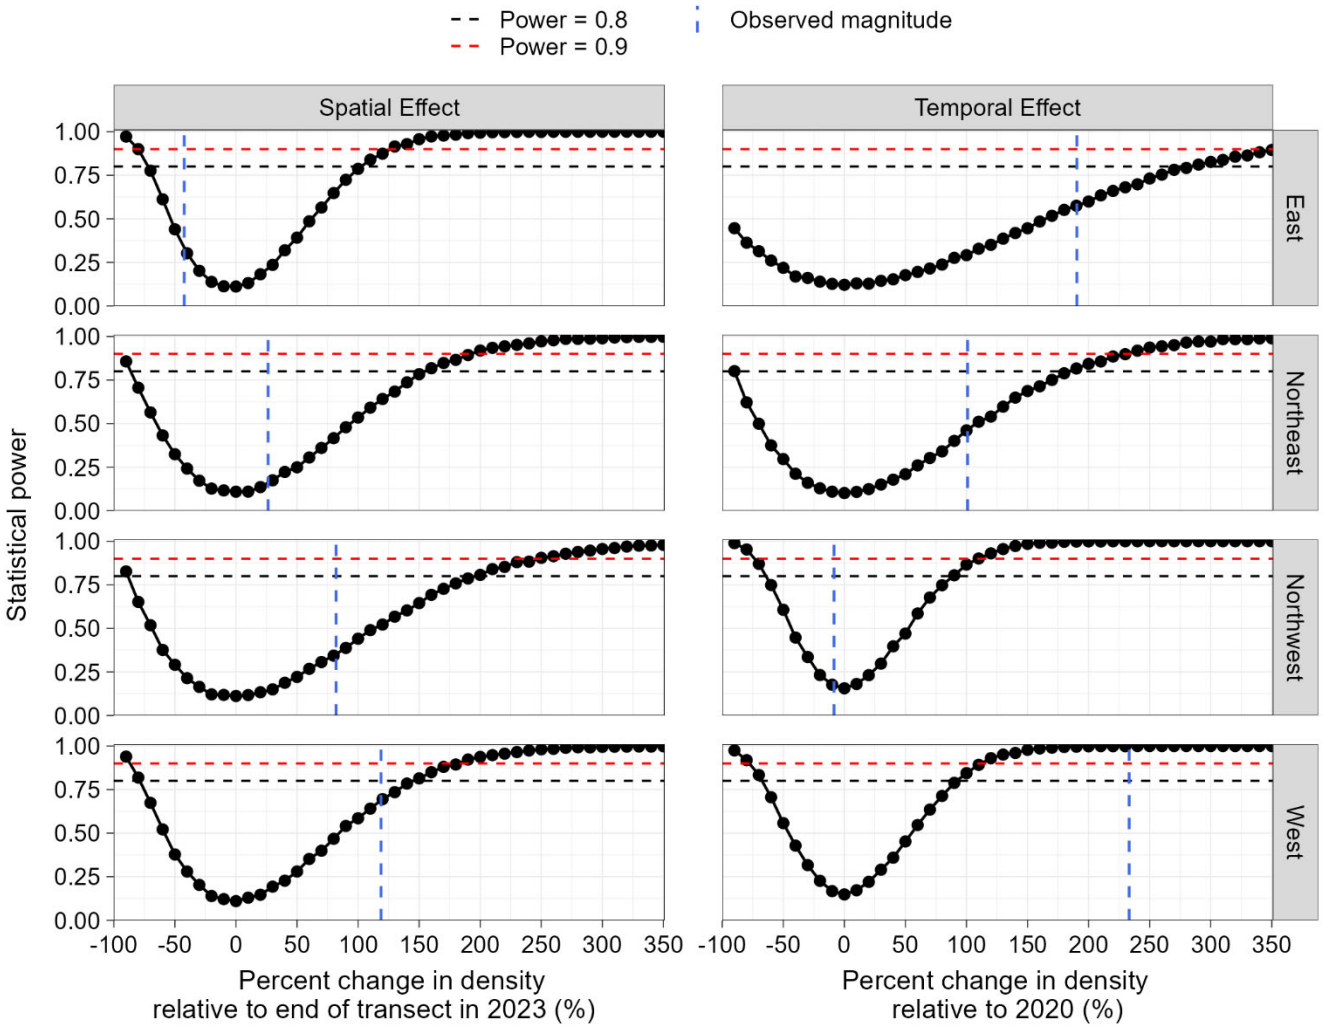

Figure 4E-2: Statistical power of the 2018-2023 density model to detect a significant spatial trend (left) and a significant temporal trend in 2023 (right). Both spatial and temporal effects were tested at 250 m (Northwest and West transects) and 500 m (East and Northeast transects) from transect origin.

Richness

The analysis of richness had sufficient power (>0.8) to detect spatial effects of decreasing richness at effect sizes ranging between -52% (for the West Transect) and -45% (for the East, and Northwest transects; Figure 4E-3). Power was also sufficient (>0.8) to detect spatial effects of increasing richness at effect sizes ranging between +57% (for the East Transect) and +75% (for the West Transect). Observed effect sizes in 2023 were -15%, +109%, +33%, and -7% for the East, West, Northwest, and Northeast transects, respectively. The model had high power (>0.9) to detect the observed effect size for the West Transects, but low power (<0.5) to detect the effect size observed at the Northwest Transect. For both East and Northeast transects, observed effect sizes were small, indicating little to no effect; consequently, statistical power to observe those was low. This is consistent with the finding of a significant increasing trend near the transect origin for West Transect in 2023, but not for the remaining transects (Section

4.4.3.2 in the 2023 MEEMP main report [WSP 2024]). The model had higher power to detect decreases in richness than increases, especially for the West Transect. Since a reduction in richness due to Project activity is of more concern than an increase in richness, the statistical power to detect reductions was considered to be more relevant.

For the temporal effects, the model had sufficient power (>0.8) to detect temporal effects of decreasing richness at effect sizes ranging between -75% (East Transect) and -37% (West Transect; Figure 4E-3). Power was also sufficient (>0.8) to detect temporal effects of increasing richness between 2020 and 2023 at effect sizes of ranging between +42% (for the Northwest Transect) and +120% (for the East Transect). Observed effect sizes were +69% and +54% for the East and West transect, respectively, and 4–5% for the Northeast and Northwest transects. Since both of the larger observed effect sizes were positive (i.e., increase in richness), the low statistical power to detect the observed effect at the East Transect was not considered a concern at this time.

Overall, power to detect spatial trends was similar to the power to detect temporal trends. The observed spatial and temporal effects at the West Transect, but not at any of the other transects, had sufficient power. Of the four transects, two had observed spatial increases in richness (i.e., higher richness at proximity to the transect origins), and two had substantial increases in richness in proximity to transect origin between 2020 and 2023.

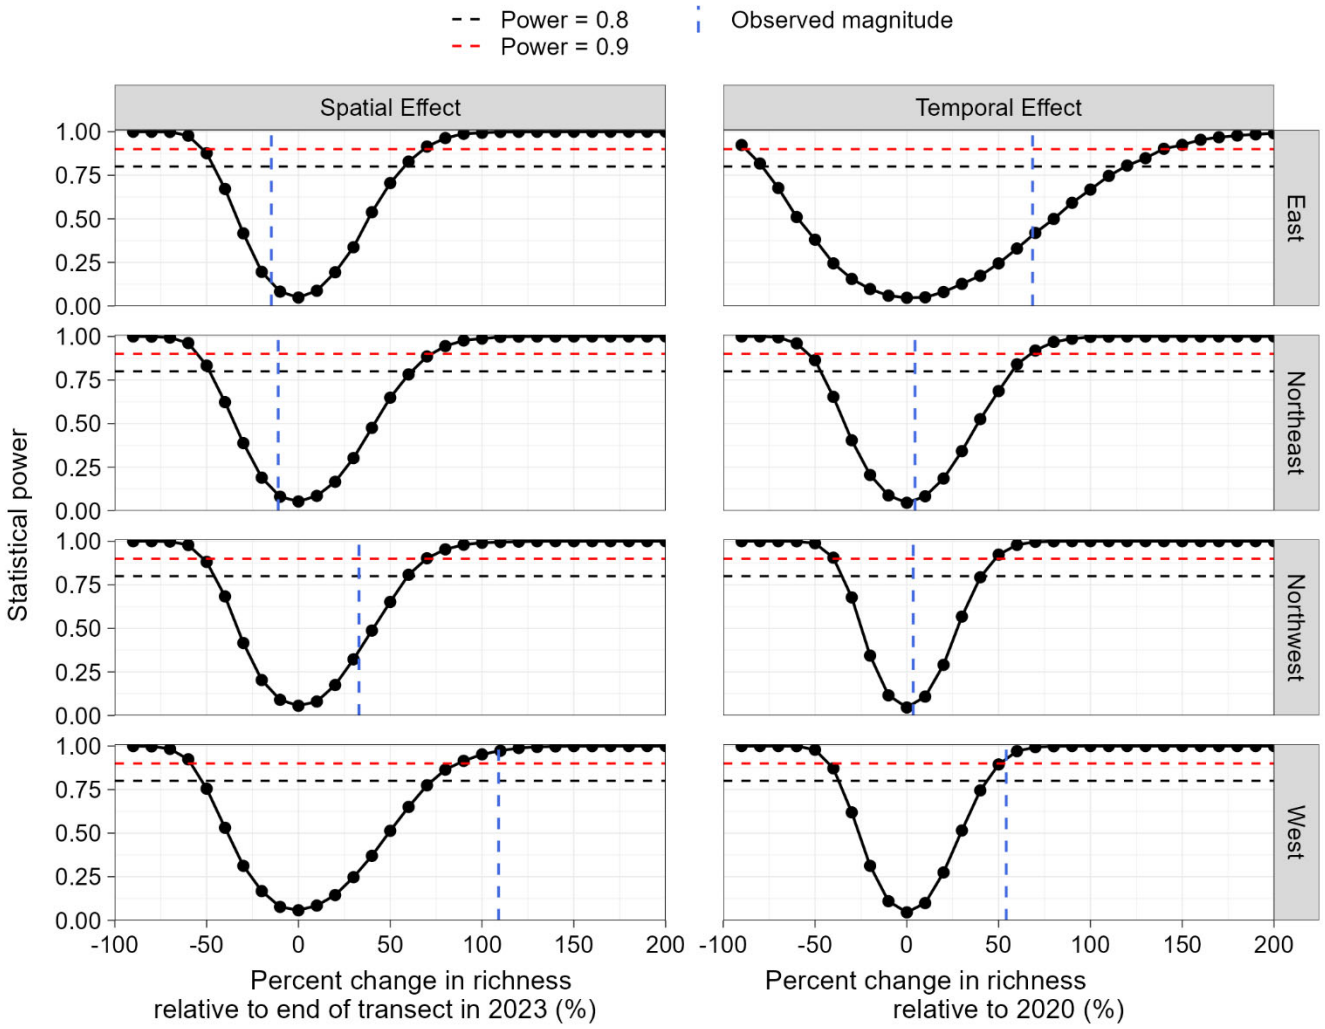

Figure 4E-3: Statistical power of the 2018-2023 richness model to detect a significant spatial trend (left) and a significant temporal trend in 2023 (right). Both spatial and temporal effects were tested at 250 m (Northwest and West transects) and 500 m (East and Northeast transects) from transect origin.

Simpson's Diversity Index

The analysis of SDI had sufficient power (>0.8) to detect spatial effects of decreasing SDI at effect sizes of -65% , -57%, -62%, and -72%, for the East, West, Northwest, and Northeast transects, respectively (Figure 4E-4. Power was sufficient (>0.8) to detect a spatial increase in SDI only at the West Transect, at an effect size of +177%. Observed effect sizes in 2023 were -62%, +362%, -28%, and -35% for the East, West, Northwest, and Northeast transects, respectively. The model had high power (>0.9) to detect the observed effect size for the West Transect, marginally insufficient power (0.76) to detect the observed effect at the East Transect, and low power (<0.5) to detect the effect size observed at the Northwest and Northeast transects. This is consistent with the finding of a significant increasing trend near the transect origin for West Transect and a section of the East Transect in 2023, but not for the remaining transects (Section 4.4.3.3 in the 2023 MEEMP main report [WSP 2024]). The model had higher power to detect decreases in SDI than increases for all four transects. Since a reduction in SDI due to Project activity is of

more concern than an increase in richness, the statistical power to detect reductions was considered to be more relevant.

For the temporal effects, the model had sufficient power (>0.8) to detect temporal effects of decreasing SDI at effect sizes of -45%, -44%, and -65% for the West, Northwest, and Northeast transects, respectively, but not at any effect size at the East Transect (Figure 4E-4). Power was also sufficient (>0.8) to detect temporal effects of increasing SDI between 2020 and 2023 at effect sizes of +82% and +110% for the West and Northwest transects, respectively, but not at the Northeast or East transects for any of the assessed effect sizes. Observed effect sizes were +331% and -44% for the East and West transect, respectively, and -22% and -2% for the Northwest and Northeast transects, respectively. The low power to detect a significant temporal effect at the East Transect is likely due to the high uncertainty associated with the 2020 estimate at the East Transect at 500 m from transect origin, as the sampling was only performed starting at 650 m from origin.

Overall, power to detect spatial trends was lower than power to detect temporal trends for three of the four transects, and for most cases, power to detect decreases in SDI was higher than power to detect increases. Only one observed spatial effect had sufficient power. Of the four transects, only the West Transect had observed spatial increases in SDI (i.e., higher SDI at proximity to the transect origin), and one had a substantial increase in SDI in proximity to transect origin between 2020 and 2023. Power to detect increases in SDI was generally low, since observed SDI values were generally high, and due to the bounding of SDI between 0 and 1, further increases in SDI would be difficult to detect.

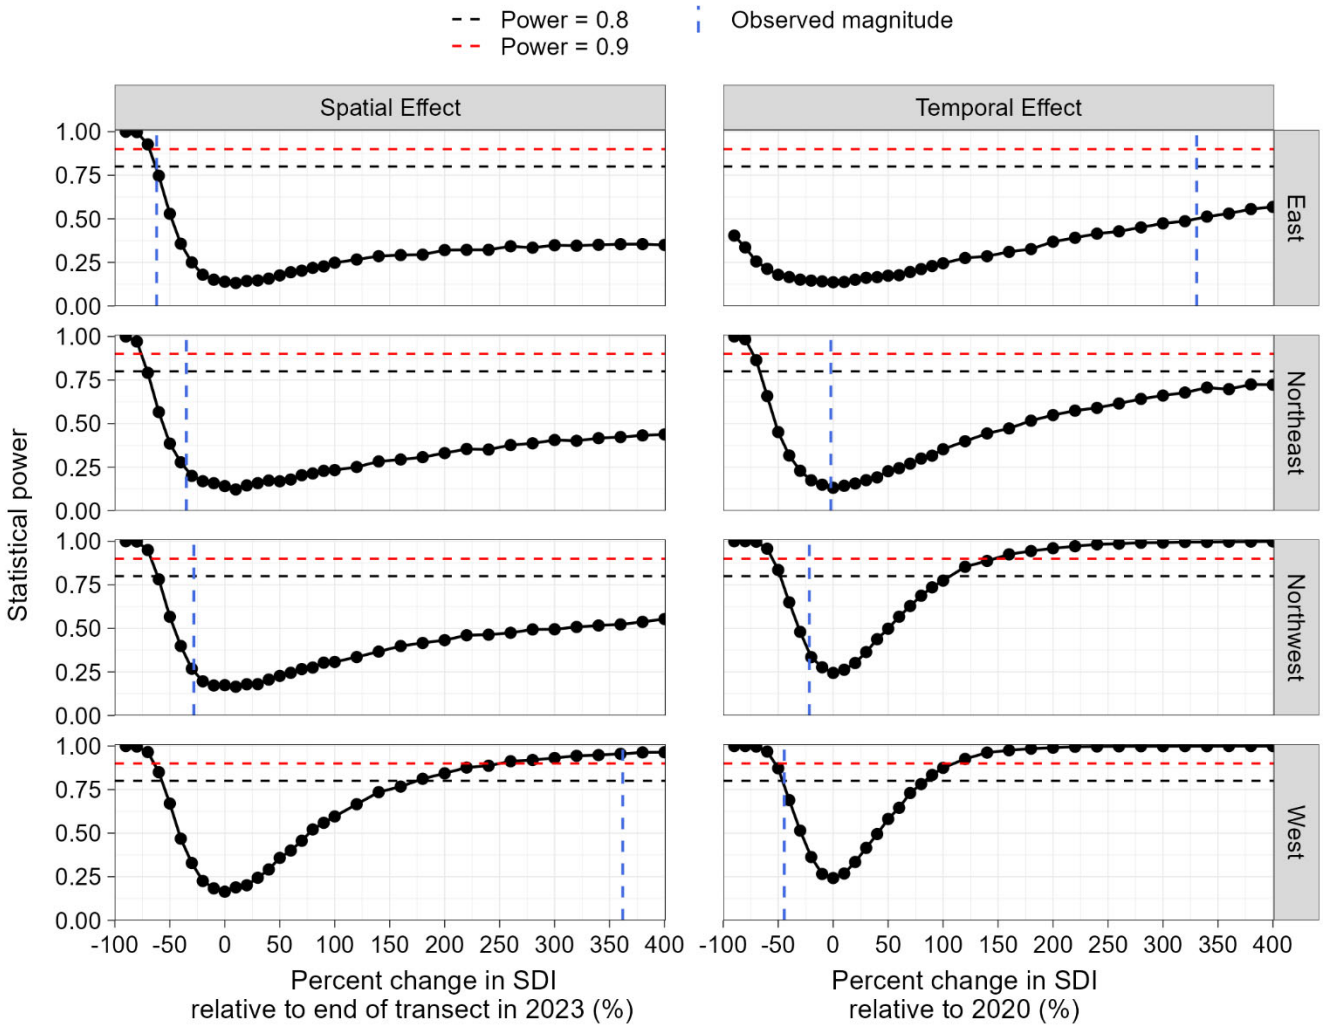

Figure 4E-4: Statistical power of the 2018-2023 SDI model to detect a significant spatial trend (left) and a significant temporal trend in 2023 (right). Both spatial and temporal effects were tested at 250 m (Northwest and West transects) and 500 m (East and Northeast transects) from transect origin.

Simpson's Evenness Index

The analysis of SEI had sufficient power (>0.8) to detect spatial effects of decreasing SEI at effect sizes of -92%, -80%, and -69% for the East, Northwest, and Northeast transects, respectively, but not for the West Transect (Figure 4E-5). Power was sufficient (>0.8) to detect a spatial increase in SEI at effect sizes of +285%, +390%, +175%, and +200% for the East, West, Northwest, and Northeast transects, respectively. The model had low power (<0.7) to detect all observed spatial effects. This is consistent with the lack of statistically significant slopes at distances of 250 m or 500 m from transect origin (Section 4.4.3.4 in the 2023 MEEMP main report [WSP 2024]). Observed effect sizes were +1% and +159% for the East and West transect, respectively, and -51% and 0% for the Northwest and Northeast transects, respectively. The model generally had higher power to detect decreases in SEI than increases. The large effect sizes required to obtain sufficient power for increasing SEI were due to the low SEI values used as

the baseline (i.e., the SEI values at the end of the transect). This was especially noticeable for the West Transect, where the 2023 SEI value at the end of the transect was only 0.06, leading to an effect size of +390% required for sufficient power. Overall, since a reduction in SEI due to Project activity is of more concern than an increase in richness, the statistical power to detect reductions was considered to be more relevant.

For the temporal effects, the model had sufficient power (>0.8) to detect temporal effects of decreasing SEI at effect sizes of -55%, -65%, and -75% for the West, Northwest, and Northeast transects, respectively, but not at any effect size at the East Transect (Figure 4E-5). Power was also sufficient (>0.8) to detect temporal effects of increasing SEI between 2020 and 2023 at effect sizes of +90%, +110%, and +170% for the West, Northwest, and Northeast transects, respectively, but not at the East transects for any of the assessed effect sizes. Observed effect sizes were +11% and -65% for the East and West transect, respectively, and -31% and -16% for the Northwest and Northeast transects, respectively. The low power to detect a significant temporal effect at the East Transect was likely due to the low SEI values and the high uncertainty associated with the 2020 estimate at the East Transect at 500 m from transect origin.

Overall, power to detect spatial trends was similar to the power to detect temporal trends for three of the four transects, and for most cases, power to detect decreases in SEI was higher than power to detect increases. None of the observed spatial effects had sufficient power. Of the four transects, only the West Transect had observed spatial increases in SEI (i.e., higher SEI at proximity to the transect origin). Power to detect increases in SEI was generally low, since observed SEI values were small, requiring increases of large percent values to detect a significant difference from the simulated 2023 values.

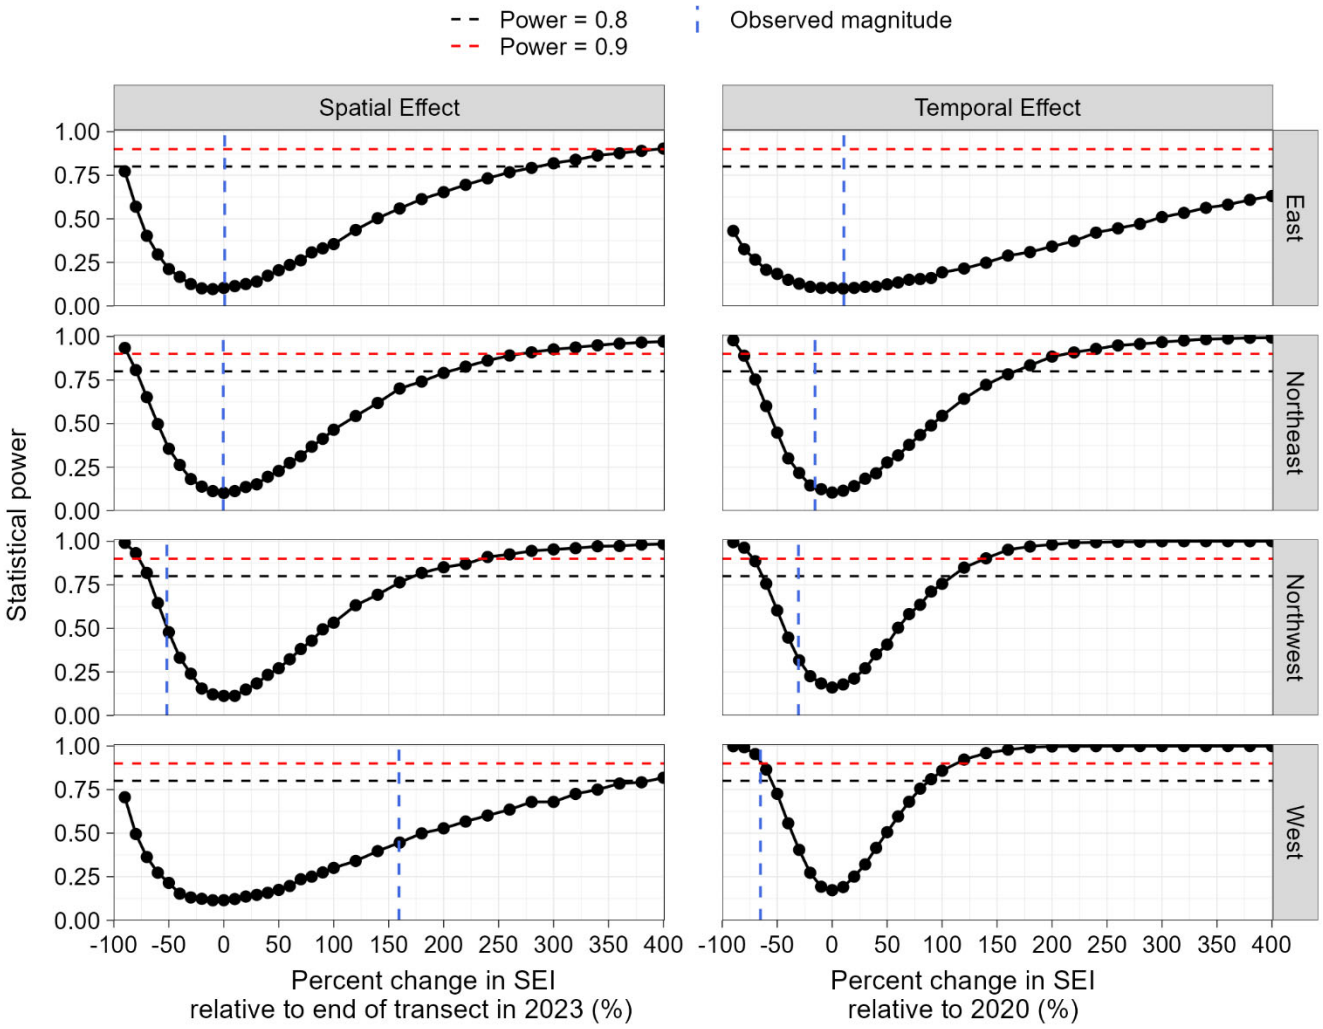

Figure 4E-5: Statistical power of the 2018-2023 SEI model to detect a significant spatial trend (left) and a significant temporal trend in 2023 (right). Both spatial and temporal effects were tested at 250 m (Northwest and West transects) and 500 m (East and Northeast transects) from transect origin.

POWER ANALYSIS – SUMMARY

Summary of Findings

- Density
  - Spatial effects: sufficient power to detect a spatial effect of reduction in density at effect sizes ranging between -85% and -72%. Sufficient power to detect increases in density at effect sizes ranging between +105% and +200%.
  - Temporal effects: sufficient power to detect a temporal effect of decreasing density at effect sizes of -90% and -67% for three of the transects (but not for the East Transect) and an increase in density ranging between 99% and 290%
- Richness
  - Spatial effects: sufficient power to detect a spatial effect of reduction in richness at effect sizes ranging between -52% and -45%. Sufficient power to detect increases in richness at effect sizes ranging between +57% and +75%.
  - Temporal effects: sufficient power to detect a temporal effect of decreasing richness at effect sizes of -75% and -37% and an increase in richness ranging between 42% and 120%.
- SDI
  - Spatial effects: sufficient power to detect a spatial effect of reduction in SDI at effect sizes ranging between -72% and -57%. Sufficient power to detect increases in SDI only at the West Transect, at effect size of +177%.
  - Temporal effects: sufficient power to detect a temporal effect of decreasing SDI at effect sizes ranging between -65% and -44% for three of the transects and an increase in SDI ranging between 82% and +110% for two of the transects.
- SEI
  - Spatial effects: sufficient power to detect a spatial effect of reduction in SEI at effect sizes ranging between -92% and -69%. Sufficient power to detect increases in SEI at effect sizes ranging between +175% and +390%.
  - Temporal effects: sufficient power to detect a temporal effect of decreasing SEI at effect sizes ranging between -75% and -55% and an increase in SEI at effect sizes ranging between +90% and +170% for three of the transects.

Implications of Power Analysis Results

- Generally, analyses of benthic infauna had higher statistical power to detect decreases, rather than increases, in values. Since reductions in benthic infauna indices are of more concern than increases, the statistical power to detect reductions was considered to be more relevant.
- Given the low statistical power to detect effect sizes that may be of biological relevance, going forward, it is recommended that conclusions are not made based on strict adherence to statistical significance. Instead, effect size, uncertainty, and statistical significance and power should be considered together before ruling out spatial and temporal changes in benthic infauna.

5.0 SUBSTRATE, MACROFLORA, BENTHIC EPIFAUNA

5.1 Introduction

This chapter presents the results of the substrate, macroflora, and benthic epifauna monitoring program, a component of the larger Marine Environmental Effects Monitoring Program (MEEMP) conducted at Milne Port and in Milne Inlet during the 2023 open-water season. The MEEMP is designed to evaluate potential Project-related effects on the marine environment as predicted in the Final Environmental Impact Statement (FEIS) and FEIS addenda (Baffinland 2012, 2013). This component was also developed in consideration of the monitoring requirements outlined in the Project Certificate (PC) Conditions described in in Chapter 1.0, Table 1-2. PC Conditions related to the monitoring of substrate, macroflora, and epifauna included PC Conditions No. 76, 83 (a), 87, 99 (a), and 99 (c).

5.1.1 Objectives

The MEEMP objectives are outlined in Section 1.3 of Chapter 1.0 (Program Overview). Objectives specific to the substrate, macroflora, and benthic epifaunal component are as follows:

- Monitor for changes in substrate conditions or in the macrofloral and benthic epifaunal community at Milne Port and in a nearby reference area for the purpose of identifying potential Project-related effects.
- Verify predictions made in the FEIS, and subsequent addenda, regarding effects on Arctic char (*Salvelinus alpinus*) habitat.
- Recommend necessary and appropriate changes to survey methodology for future years, if warranted.

5.2 Study Design

5.2.1 Background

The 2014 to 2017 MEEMP study design monitored for changes to the benthic community with epifauna[1] and epiflora[2] as indicators, using towed underwater video transect surveys. The use of epifauna and epiflora as effect indicators deviated from the standard Environmental Effects Monitoring (EEM) methodology (Environment Canada 2010; 2012) and presented a number of challenges, including 1) high temporal and spatial variability due to the mobile and transient nature of many epifaunal species, 2) typically low resolution of video survey data compared to laboratory analysis for species identification, enumeration and substrate classification, and 3) difficulty in distinguishing between live epiflora (e.g., kelp) and detrital vegetation debris using video survey methods, which can result in inaccurate results.

In 2018, a new survey design was implemented, based on a Before-After-Control-Impact (BACI) approach. A reference area had been established in 2013 and selected for its proximity to Milne Port while residing outside of the main zone of influence (ZOI) of Project activities (SEM 2014). Towed underwater video transects were replaced with five belt transects (1 m x 5 m plots) permanently installed on the seabed in each exposure (impact) and reference (control) areas. Monitoring was conducted using a remotely operated vehicle (ROV) underwater

[1] Benthic invertebrates living on the substrate.

[2] Marine vegetation attached to the substrate (e.g. kelp).

video system. In addition to informing this component of the MEEMP, taxonomic data were also used to inform the Non-Indigenous Species and Aquatic Invasive Species (NIS/AIS) program (Chapter 8.0). In 2019, underwater video monitoring of epifauna and macroflora communities within permanent belt transects continued for a second year. The belt transects deployed in 2018 were composed of two 1 m-long, 5 cm-diameter aluminum pipes filled with concrete connected by two steel chains, 5 m in length, attached to both ends of the pipes (Figure 5-1A). In 2019, it was determined that the flexible design was not suitable for the environment, as five of the ten deployed transects had been dragged from their original position due to presumed interactions with the sea-ice during spring break-out or had become embedded in the sediment and thus obscured from video detection (Figure 5-1B).

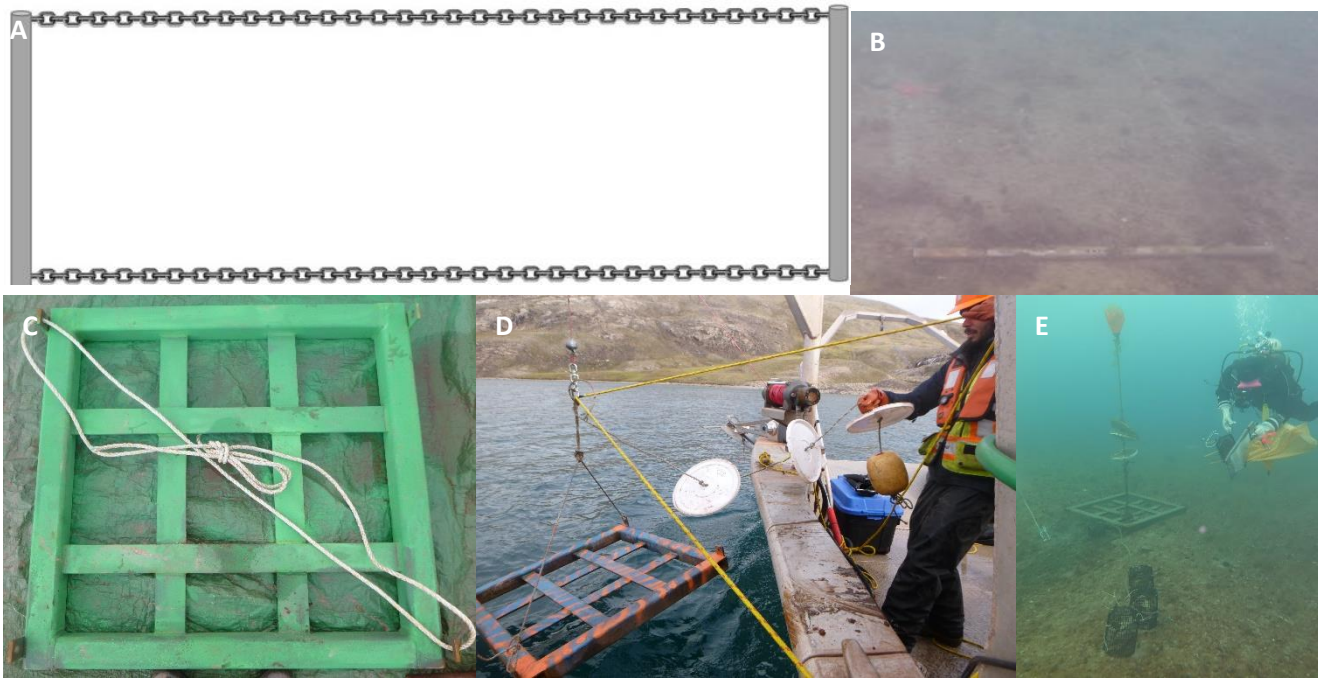

Figure 5-1: A) Diagram of Belt Transects Used for Macroflora and Epifauna Surveys in 2018 – 2019; B) Deployed Belt Transect; C) Example of 1 x 1 m Steel Quadrat Deployed in 2021; D) Active Deployment of Survey Quadrat; and E) Underwater Photo of Quadrat (Q4) With Attached Settlement Substrates for NIS/AIS Monitoring.

The program was modified in 2020 to replace the belt transects, which had been determined to be ineffective due to being dragged out of position. Modifications to the program in 2020 included the use of divers to undertake biophysical surveys of permanent, heavy-duty steel quadrats to improve the resolution of taxonomic identification. A total of ten 1 m x 1 m square quadrats were fabricated onsite in 2020 and installed on the sea bottom in Milne Port, five in the exposure area (Q1 through Q5) and five in the reference area (Q6 through Q10) (Figure 5-1C-E; Figure 5-2). An additional ten square steel quadrats were fabricated and deployed in 2021 (Q11 through Q20; five in each exposure and reference area), doubling the total number of quadrats relative to 2020. Six new permanent quadrats, Q21 through Q26, were deployed (three in each of the exposure and reference areas) in 2022, to increase statistical power and address Marine Environment Working Group (MEWG) Comment No. 05 from the 2021 MEEMP and NIS/AIS Monitoring Program Report (Golder 2022). This modification expanded the total number of quadrats to 13 in each area (Figure 5-2).

Additionally, starting in 2020 as part of the Chapter 8.0 NIS/AIS program, settlement substrates were co-located and deployed with the quadrats to monitor for short- and medium-term recruitment of encrusting taxa. Settlement substrates consisted of settlement plates attached to a line with a subtidal buoy, and cobble-filled settlement baskets attached to a corner of the quadrat, as described in Chapter 8.0. Additional quadrats deployed in 2022, Q21 through Q26, are not co-located with Chapter 8.0 NIS/AIS settlement substrates.

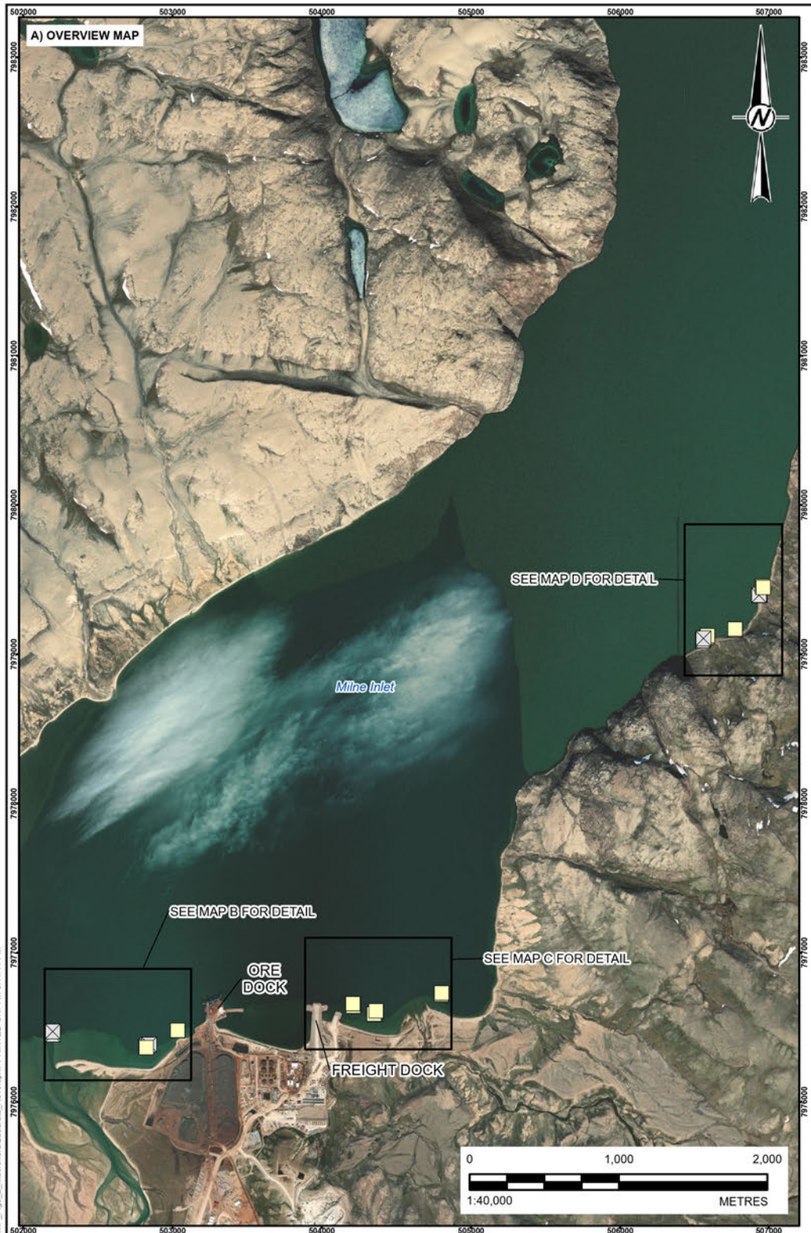
In previous years, taxonomic resolution was relatively coarse because of poor visibility due to suspended particles in the water column and the use of a ROV-based underwater video survey for monitoring. Survey of the quadrats was performed by a combination of divers and ROV in 2020[3] and exclusively by divers in 2021 to 2023. The rationale for discontinuing the ROV was that divers were more accurately able to distinguish unique taxa, differentiate between detrital algae or non-living organisms versus living organisms, move vegetation aside to observe the underlying substrate and marine organisms, and collect specimens from the quadrats for identification purposes.

Surveys conducted in 2020 indicated that Q9 had been originally deployed over hard substrate (boulder) and supported different ecological communities relative to the soft substrate quadrats. Therefore, in 2021, Q9 was relocated to a different area to maintain comparability between quadrats.

During the 2021 field program, divers were unable to locate Q2 after undertaking a thorough search between the -3 and -12 m CD (chart datum) depth contour (Q2 was deployed at approximately -10 m CD), extending approximately 25 m to the west and east of the original location. This quadrat was assumed to have been dragged from its original position by sea-ice. A replacement quadrat (Q2) was deployed at -12 m CD in 2022 with co-located settlement substrates. Surveys conducted in 2021 also noted that Q12 had been deployed too shallow (-6 m CD) from desired target depth (-7 to -9 m CD) and, consequently, the Q12 quadrat data was not included in analyses in 2021. Quadrat Q12 was relocated to deeper water in 2022 (with co-located settlement substrates) to maintain comparability between quadrats, as per recommendations in Golder (2022).

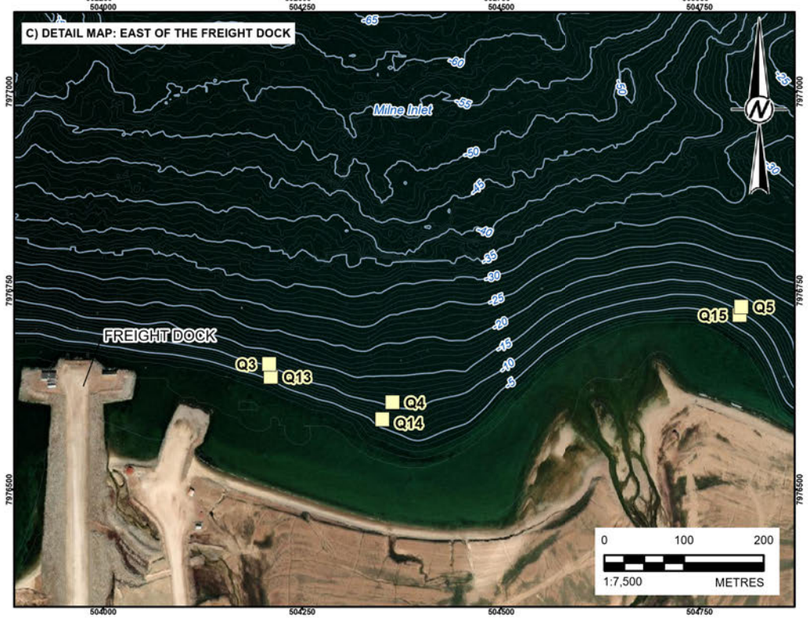
During the 2022 field program, the vessel anchor had been deployed and caught on Q16, causing it to drag across the bottom to a new location in -9.1 m CD from the original -5.7 m CD depth. Divers observed that the sediment surface was disturbed inside and outside the quadrat and the data collected during the 2022 quadrat survey indicated that less silt was observed compared to 2021 and that infauna, such as clams, had been brought up to the sediment surface. Therefore, Q16 results from 2022 were considered an outlier and removed from analyses. One objective of the field program in 2023 was to relocate Q16 to a new location at a similar depth as the original location in 2021 (-5.7 m CD) with a new quadrat name to restart the quadrat data series. Relocation was not possible in 2023 due to field program constraints.

5.2.2 Modifications to the Program (2023)

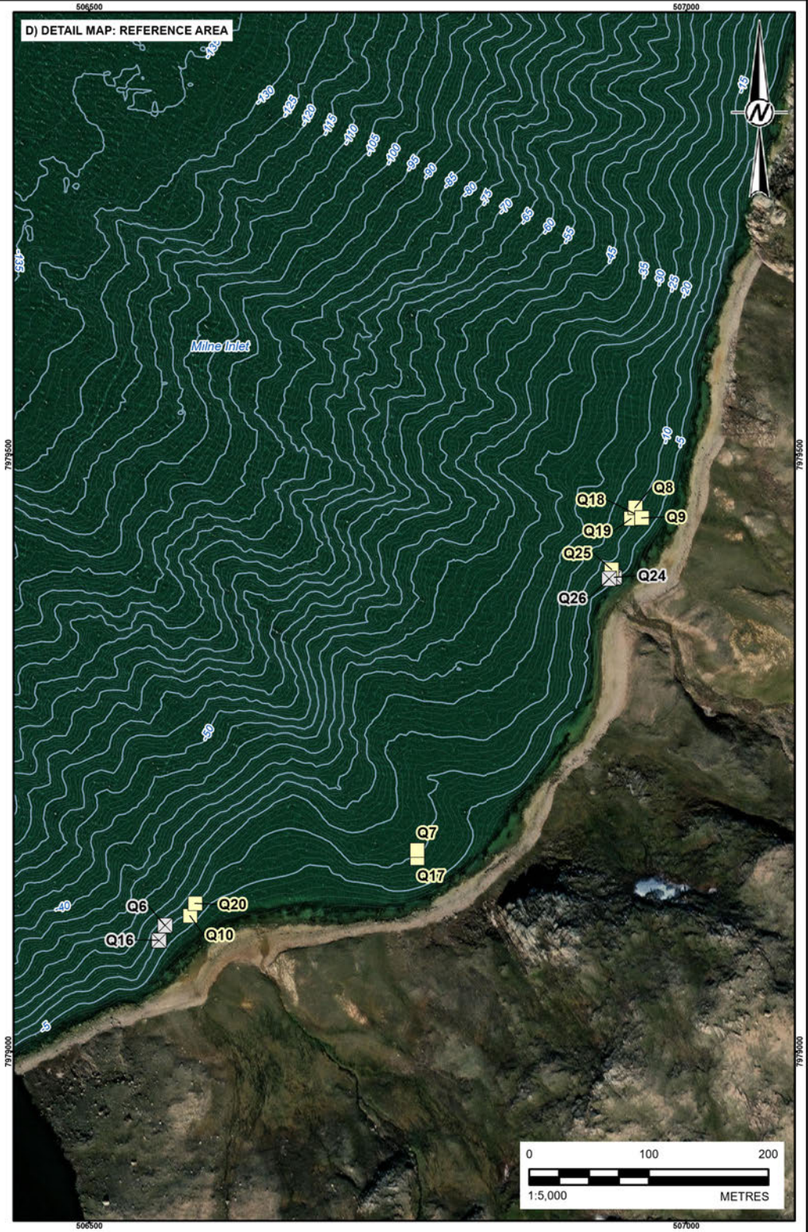


There were no survey design modifications to the program in 2023; however, the start of the field program was delayed by late ice breakup, vessel repairs, and a minor illness (with mandatory quarantine to rule out COVID). Consequently, only 18 out of the 26 quadrats could be surveyed.

[3] Divers surveyed quadrats in the reference area (Q6, Q8, Q9, Q10), but were unable to survey the quadrats in the exposure area due to time constraints in the field program (these were subsequently completed using ROV-video surveys).



5.2.3 Indicators



Effect indicators selected to evaluate potential Project-induced changes in substrate, macroflora and epifauna include taxa richness (number of unique taxa present), relative abundance, Simpson's Diversity Index (SDI), density (motile taxa) and percent cover (macroflora and sessile invertebrates). These indicators are described in detail in Section 5.3.2.1. The indicators were calculated from data collected in both reference and exposure areas and analyzed statistically to evaluate Project-related effects within the study area.

Changes in field methodologies over time (as explained in Section 5.2.1), preclude the ability to make quantitative temporal comparisons to years prior to 2021. The 2021 quadrat survey results served as a benchmark for quantitative comparisons for future monitoring years so long as field methodologies remain consistent.

5.3 Materials and Methods

5.3.1 Field Methodology

Twenty-six 1 m x 1 m square steel quadrats[4] were fabricated on site and lowered to the sea floor from a vessel: thirteen quadrats in each of the exposure area and reference area (Table 5-1, Figure 5-2). Ten quadrats (Q1 through Q10) were deployed in 2020, ten additional quadrats were deployed in 2021 (Q11 through Q20), and six additional quadrats were deployed in 2022 (Q21 through Q26). In each case, annual surveying commenced in the year of deployment. Further, a replacement quadrat was deployed in 2022 at a new location to replace Q2 which had not been recovered in 2021. The quadrats were deployed from the field vessel at the locations of the previous belt transects, in water depths of approximately -4 to -18 m CD. Each quadrat was marked with fluorescent spray paint to aid in relocating them in subsequent surveys and with quadrat-specific identifying features to identify quadrat number to the divers[5]. With the exception of Q12, quadrats were deployed in pairs or clusters so that more than one quadrat could be surveyed on a single dive.

Field surveys of the quadrats were conducted in late June to early August 2023 by WSP's occupational (SCUBA-based) dive team composed of marine biologists. The dive team is certified in accordance with Canadian Standard Association Z275:4-97, and WorkSafe BC Regulations Part 24. A single diver carried out all data recording (identification and quantification of substrate type and taxa) to ensure consistency, while the second diver collected photographic records. Dive surveys were conducted from Baffinland's 9 m research vessel.

Field surveys included the following components:

- Subtidal dive quadrat surveys to quantitatively evaluate macroalgae, sessile and motile invertebrates and fish occurrence (commonly termed epifauna) within both the exposure area and reference area.
- Opportunistic observations[6] of macroalgae, fish and motile/sessile invertebrates during quadrat surveying.
- Opportunistic specimen collection of macroalgae, fish and motile/sessile invertebrates to enhance taxonomic resolution, particularly in cases where organisms may be suspected to be non-indigenous to the area.

[4] The quadrat frames are approximately 1 x 1 m but the survey area excludes the metal sub-grid bars (see Section 5.3.1.1). 2020/2021-fabricated quadrats have a survey area 0.44 m^2; the 2022-fabricated quadrats have a survey area 0.64 m^2.

[5] Quadrats Q1 through Q10 have anchor chain suspending the settlement plates, while quadrats Q11 through Q20 have polyurethane line. Quadrats Q21 through Q26 do not have co-located settlement plates and have unique buoys associated with each quadrat. Quadrats Q11 through Q20 also have tactical markers to indicate the specific quadrat.

[6] Opportunistic observations refer to observations that were recorded during diver-collected photo or video to document presence/absence in a qualitative manner rather than quantitatively assessed during the quadrat survey.

Table 5-1: Quadrat Locations in Milne Port (2023)

Area	Quadrat	UTM Coordinates (17W)		Depth (-m below CD)[1]	Deployment Date	Survey Date (2023)
		Easting (m)	Northing (m)			
Milne Port (Exposure)	Q1	502828	7976382	8.8	12 August 2020	27 July
	Q2	502843*	7976385*	12.3*	9 August 2022	Not surveyed
	Q3	504208	7976659	10.2	12 August 2020	31 July

	Q15	504800	7976721	6.8	6 August 2021	26 July
	Q21	502197*	7976453*	6*	6 August 2022	Not surveyed
	Q22	502198*	7976473*	10*	6 August 2022	Not surveyed
	Q23	502823	7976365	4	6 August 2022	27 July
Reference Area	Q6	506563*	7979107*	18.3*	13 August 2020	Not surveyed
	Q7	506774	7979170	9.9	13 August 2020	29 July
	Q8	506957	7979457	10.3	13 August 2020	29 July
	Q9	506962	7979448	7.9	11 August 2021	29 July
	Q10	506584	7979115	6.4	13 August 2020	31 July
	Q16	506558[2]*	7979093[2]*	9.1*	8 August 2021	Not surveyed
	Q17	506774	7979163	8.6	11 August 2021	29 July
	Q18	506956	7979452	9.7	11 August 2021	29 July
	Q19	506953	7979447	10.1	11 August 2021	29 July
	Q20	506588	7979125	10.4	8 August 2021	31 July
	Q24	506939*	7979398*	8.1*	7 August 2022	Not surveyed
	Q25	506937*	7979405*	9.8*	7 August 2022	Not surveyed
	Q26	506935*	7979397*	9.1*	7 August 2022	Not surveyed

Note: '*' indicates coordinates and depth data are reported from 2022 as these quadrats were not surveyed in 2023.

[1] Diver depth gauge was converted to meters chart datum (CD), estimated using tide table for Milne Inlet, Nunavut (https://tides.gc.ca/en/stations/05791 [accessed November 2023]). The negative (-) numbers indicate 'below' CD.

[2] Q16 had moved to deeper depths in 2022 due to vessel anchor dragging the quadrat.

5.3.1.1 Quadrat Survey

Biophysical data within each quadrat were recorded by one diver while another diver collected representative photographs[7] of the quadrat (Appendix 5B – Photo 1). Observations were made of the quadrat as a whole[8] as opposed to surveying each sub-quadrat individually (as was done in 2021) to increase survey efficiency and remain standardized for multi-year comparisons. The area covered by the metal sub-grid bars[9], or organisms sitting on top of the sub-grid bars or on the outside steel frame of the quadrat were not surveyed.

Quantitative data were collected in general accordance with Fisheries and Oceans Canada's (DFO) Marine Foreshore Environmental Assessment Procedure (MFEAP) (Appendix 5A). Quadrat data were recorded on project-specific datasheets, and included the following information:

- Substrate type was visually estimated according to the following size ranges derived from Wentworth (1922) and recorded as relative composition (i.e., as a percent areal coverage): bedrock; boulder (>256 mm diameter); cobble (64 to 256 mm); gravel (2 to 64 mm); and soft substrate[10] (<2 mm). The combination of sand and silt categories into a single soft substrate (<2 mm) category was done in 2023 as separation of these two categories was demonstrated to be subjective and prone to diver error.
- Total percent cover of detritus and debris was calculated separately from substrate composition as it overlaid the existing substrate. Detritus and debris were categorized into three groups: detrital veneer, detrital macroalgae, and other debris (i.e., metal). Detrital veneer is organic material and appears to consist of phytoplankton/diatoms and silt.
- Macroalgae were identified to the lowest practical level (LPL) and total areal coverage was estimated.
- Sessile invertebrates (e.g., clams and mussels) were identified to LPL and total areal coverage was estimated (as above).
- Motile invertebrates (e.g., urchins, limpets) and fish were identified to LPL and enumerated. Abundance was estimated if relatively large numbers (typically, numbers exceeding 100, depending on size and behaviour of organisms) of motile species were present.
- Photographs showing representative biological features and aiding in species identification were taken.

5.3.1.2 Opportunistic Specimen Collection

Opportunistic samples of epifauna and macroflora were collected to improve species identifications, which is particularly important if this sampling method is to effectively detect species that might be non-indigenous to the area. Specimens were collected using the following protocol:

[7] Underwater imagery collected using a SONY RX100 V camera in Fantasea underwater housing and Big Blue video light for all underwater surveys. The camera has high-definition video capability and still photography features.

[8] Survey area excludes the area covered by the metal sub-grid bars (Figure 5-2). Organisms on or beneath the metal sub-grid bars were excluded from quadrat data (and noted as opportunistic observations) unless they entered the survey area during the survey.

[9] The sub-grid bars were used during the 2021 ROV surveys to systematically photograph the quadrat.

[10] Sand (0.0625 to 2 mm) and silt/mud/clay (<0.0625 mm) were combined into one category of soft sediment in 2023 due to constraints in the field determining exact grain size through dive gloves and misalignment of Chapter 5.0 and Chapter 3.0 (Sediment Quality) results in previous years. Data from 2022 and 2021 were adjusted to follow this change.

- Divers collected specimens in sealed plastic bags or small vials and brought these to the surface in a mesh bag.
- Discretion was used to sample only one to two representative individual(s) to avoid over-harvesting from the quadrats which could have future implications on the community assemblage (experimental design interaction).
- Samples were placed into 50 mL or 120 mL clear glass jars and preserved in a 10% buffered formalin solution. This concentration has been confirmed to be appropriate for initial preservation of specimens for DNA analysis by the Canadian Centre for DNA Barcoding (T. Macdonald, Biologica Environmental Services Ltd, pers. comm.). The jars were then sealed and inverted several times to promote homogenization and saturation with the preservative. Jars were labeled internally and externally with water-resistant labels.
- Samples were sent to Biologica Environmental Services Ltd. (Biologica) for taxonomic identifications.

5.3.2 Data Analysis

Diver-collected quadrat data were entered into an electronic database by one biologist and verified by a second biologist to reduce transcription errors. Some taxa observed were neither epifauna nor benthic, such as pelagic taxa (mysid shrimp, sea angels), and hence considered “incidental” and not included in data analysis. Field-based identifications were updated where lab identifications of opportunistically sampled specimens resulted in improved taxonomic resolution. Further, identifications were verified and updated, as necessary, with photographs taken from the field.

Data analysis was based on separating biota by three assemblages, defined as taxa that share an attribute of habitat or taxonomic similarity, and representing subsets of a biological community: macroflora, sessile epifauna, and motile epifauna. Results are therefore presented by these three assemblages in Section 5.4.

Statistical analysis was based on four indicators: taxa richness (to the lowest practicable level), SDI, organism density (motile epifauna) and percent cover (macroflora and sessile epifauna). In addition, assemblages were explored as relative abundance, by grouping related taxa into broader taxonomic classifications (e.g., grouping all fish taxa into the broader classification ‘fish’) to evaluate how proportions of these major classifications might differ between exposure and reference area. Quantitative statistical analyses were performed comparing results from 2021 to 2023. Due to inconsistent sampling methodologies in previous survey years, a quantitative statistical analysis was not possible for pre-2021 survey years.

5.3.2.1 Community Indicators

Taxa Richness

Richness is defined as the total number of unique[11] taxa per quadrat. This metric provides an indication of the diversity (number of different species) in the local ecological community. A higher richness value typically indicates a healthier and more balanced community. Mean taxa richness and standard error of the mean was calculated based on number of taxa by area (exposure, reference).

Simpson's Diversity Index

Simpson's Diversity Index (SDI) measures the proportional distribution of organisms in the community. The SDI considers the abundance patterns and taxonomic richness of the community. Certain conditions may favour one taxon over another, resulting in the community being dominated by a few taxa, which is reflected in decreased diversity (Simpson 1949). The SDI values range between zero and one, where lower values indicate a less diverse community and higher values indicate a more diverse community. The SDI was calculated using the formula provided by Krebs (1999):

$$SDI = 1 - \sum_{i=1}^{S} (p_i)^2$$

Where:

- SDI = Simpson's Diversity Index
- S = the total number of taxa
- p_i = the proportion of the i^{th} taxon (of each unique taxon out of the total abundance of the sample)

For categorization, SDI values <0.250 were considered to have very low diversity, 0.250 to 0.499 had low diversity, 0.500 to 0.750 were moderately diverse and >0.750 were considered to have high diversity (Table 5-2). Mean SDI and standard error of the mean were calculated for each exposure and reference areas.

Table 5-2: Diversity Categories for Simpson's Diversity Index (SDI) Values

SDI Value	Diversity Category
<0.250	Very Low
0.250 through 0.499	Low
0.500 through 0.750	Moderate
>0.750	High

[11] Did not include higher order taxa for which there exists a lower order identification. For example, does not include *Mya* sp. if *Mya truncata* is found in the same quadrat.

Organism Density

For motile invertebrates and fish (collectively motile epifauna), density was standardized to organisms/m^2 using a correction factor for quadrat size to maintain comparability. Newly fabricated quadrats in 2022 were larger than those fabricated in 2020 and 2021. The survey area (excluding the metal sub-grid bars; Figure 5-1) of the 2020/2021 quadrats was 0.44 m^2 while the 2022-fabricated quadrats had a survey area of 0.64 m^2. Therefore, correction factors have been applied to quadrats during data analysis to standardize results to 1 m^2. Mean density (organisms/m^2) and standard error of the mean were calculated separately for exposure and reference areas.

Percent Cover

For macroalgae and sessile epifauna, mean percent areal cover (total cover) and standard error of the mean was calculated separately by area (exposure, reference). Relative abundance was calculated as percent cover standardized out of 100% for substrate, macroflora, sessile and motile epifauna.

Relative Abundance

Relative abundance is the proportion that a taxa or grouping contributes to the total abundance (standardized as a percentage). Dominant taxa (e.g., wrinkled rock borers [*Hiatella arctica*], brittle stars [Ophiuroidea indet.]) were kept at the lowest practical level while less commonly observed and/or easily grouped taxa were rolled into broader taxonomic classifications (e.g., grouping all fish taxa into the broader classification ‘fish’).

5.3.2.2 Statistical Analysis

Generalized Linear Mixed Models (GLMMs)

Differences in substrate, detritus and debris, macroalgae, and benthic epifauna indicators between the exposure and reference areas and between the survey years 2021, 2022, and 2023 were analyzed using Generalized Linear Mixed Models (GLMMs). These models were chosen due to their ability to account for both fixed and random effects, making them suitable for repeated measure studies where quadrats are resampled across time. The fixed effects in our models included the categorical explanatory variables of years, area (exposure and reference area), and substrate type, and the continuous explanatory variable of depth; the random effect was quadrat. The models incorporated an interaction term (Year*Area) to assess whether area effects varied across different years. Model selection for finding the best fitting model was performed using Akaike’s Information Criterion weights. The three models compared included the following explanatory variables:

1) y ~ Year * Area + (1 | Quadrat)

2) y ~ Year * Area + ns(substrate) + (1 | Quadrat)

3) y ~ Year * Area + ns(Depth) + (1 | Quadrat)

For count and density data, Poisson or negative binomial distributions were used, while beta regression was employed for percent and substrate data. To ensure the absence of collinearity among the explanatory variables, Variance Inflation Factor (VIF) values were calculated, with values below three indicating no collinearity, as per the guidelines of Zuur et al. (2007).

The models were further checked for overdispersion and outliers. Pairwise comparisons were conducted (1) between years within quadrats and (2) between areas within a year, to describe effect sizes. After fitting the GLMM, estimated marginal means were calculated to perform pairwise comparisons to compare areas within each year and across all years.

A p-value <0.05 is considered to indicate significance between groups. The statistical analyses were conducted using R Studio (R version 4.3.2; R Studio 2023) with the packages glmmTMB (Version: 1.1.8; Brooks et al. 2017), DHARMa (Version: 0.4.6; Hartig 2022), and emmeans (Version 1.10.0; Lenth 2020).

Taxa Accumulation

A taxa accumulation curve was calculated for quadrats surveyed in each year from 2021 to 2023 to provide an estimate of the effort required to fully characterize the epibenthic community assemblage. A taxa accumulation curve illustrates how the number of unique taxa (or species) increases as the number of samples are accumulated; in other words, the harder one looks (i.e., the higher the sampling effort), the more unique taxa are found. The curve reaches an asymptote when all taxa within the given community assemblage have been sampled and the community assemblage is assumed to have been fully described. The observed species (or taxa) curve is plotted and the sample (i.e., quadrat) order is randomized and permutated 999 times, resulting in an averaged curve describing a smooth relationship of the average number of species (or taxa) for each number of replicates and the standard deviation of the mean (i.e., permutations). This is equivalent to station-based rarefaction curves. Analysis was conducted using R statistical software version 4.3.2 (R Core Team 2023).

Power Analysis

A power analysis was performed using the 2021 to 2023 data using simulation methods. A detailed methodology is provided in Appendix 5E.

5.3.3 Quality Management

Quality assurance and quality control (QA/QC) procedures were applied to the field collection, data analysis, and reporting tasks within the chapter component to verify that the data presented were valid and of acceptable quality to address objectives stated in Section 5.1.1.

Field QA/QC

QA/QC measures for quantitative and qualitative data collected during quadrat surveys included:

- Field survey data sheets were checked and cross-validated in the field.
- Taxonomic identifications, including common and species name, were verified using references[12].
- Dive survey video, photographs and datasheets were saved to a laptop computer and external hard drive at the end of each field day. Once in the office, the survey data were uploaded to an internal SharePoint site.

[12] References used during the surveys included but were not limited to: Coad and Reist (2018); Golder (2021, 2022); Guiry and Guiry (2021); Küpper et al. (2016); Mecklenburg et al. (2007); WoRMS (2021), WSP (2023).

Laboratory and Data Analysis QA/QC

The following QA/QC measures were implemented:

- Taxa common name/species name and recorded observations were verified using references[12].
- Transcribed diver-collected data was reviewed for transcription errors by a second biologist.
- Calculations were verified by a second biologist for errors as part of the data review process.

5.4 Results

This section presents results from the 2023 quadrat sampling program at Milne Port, with a quantitative comparison to 2021 and 2022 data. Representative photographs are provided in Appendix 5B. Quadrat/transect data in tabulated form are presented in Appendix 5C for 2021, 2022, and 2023. Results of statistical analysis of substrate macroflora, and benthic epifauna endpoints are provided in Table 5-3, with post hoc pairwise comparison results provided in Table 5-4. A taxa list with common and scientific names is provided in Appendix 5D. Taxonomic results in relation to the objective of monitoring for non-indigenous species are presented in Chapter 8.0 (NIS/AIS).

5.4.1 Substrate

Substrate Composition

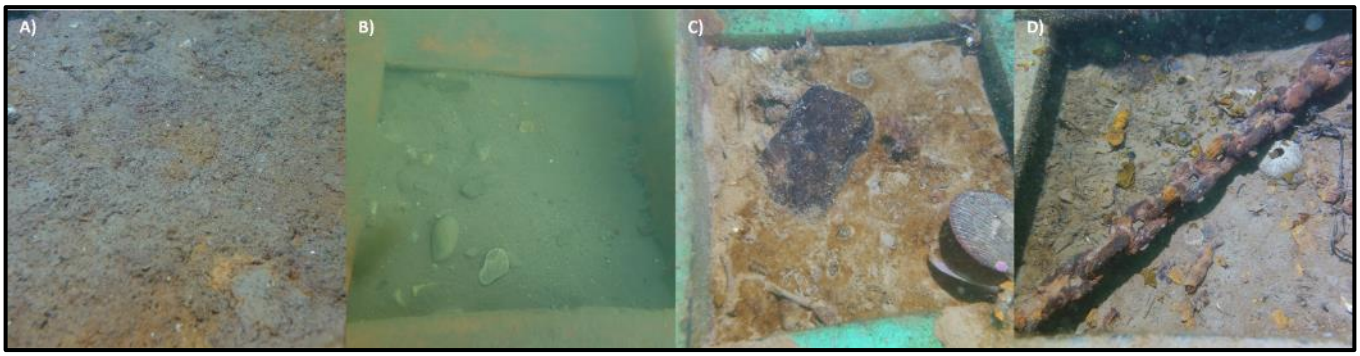
Substrate, as visually estimated by the divers using a modified Wentworth scale (Wentworth, 1922), was composed predominantly of soft substrate (silt and sand; Figure 5-3A) for quadrats in both the exposure and reference areas, as observed in previous years (Figure 5-4). Quadrat Q23 within the exposure area contained mainly sand (60%), while silt was more dominant in the other quadrats within both areas (Appendix 5C).

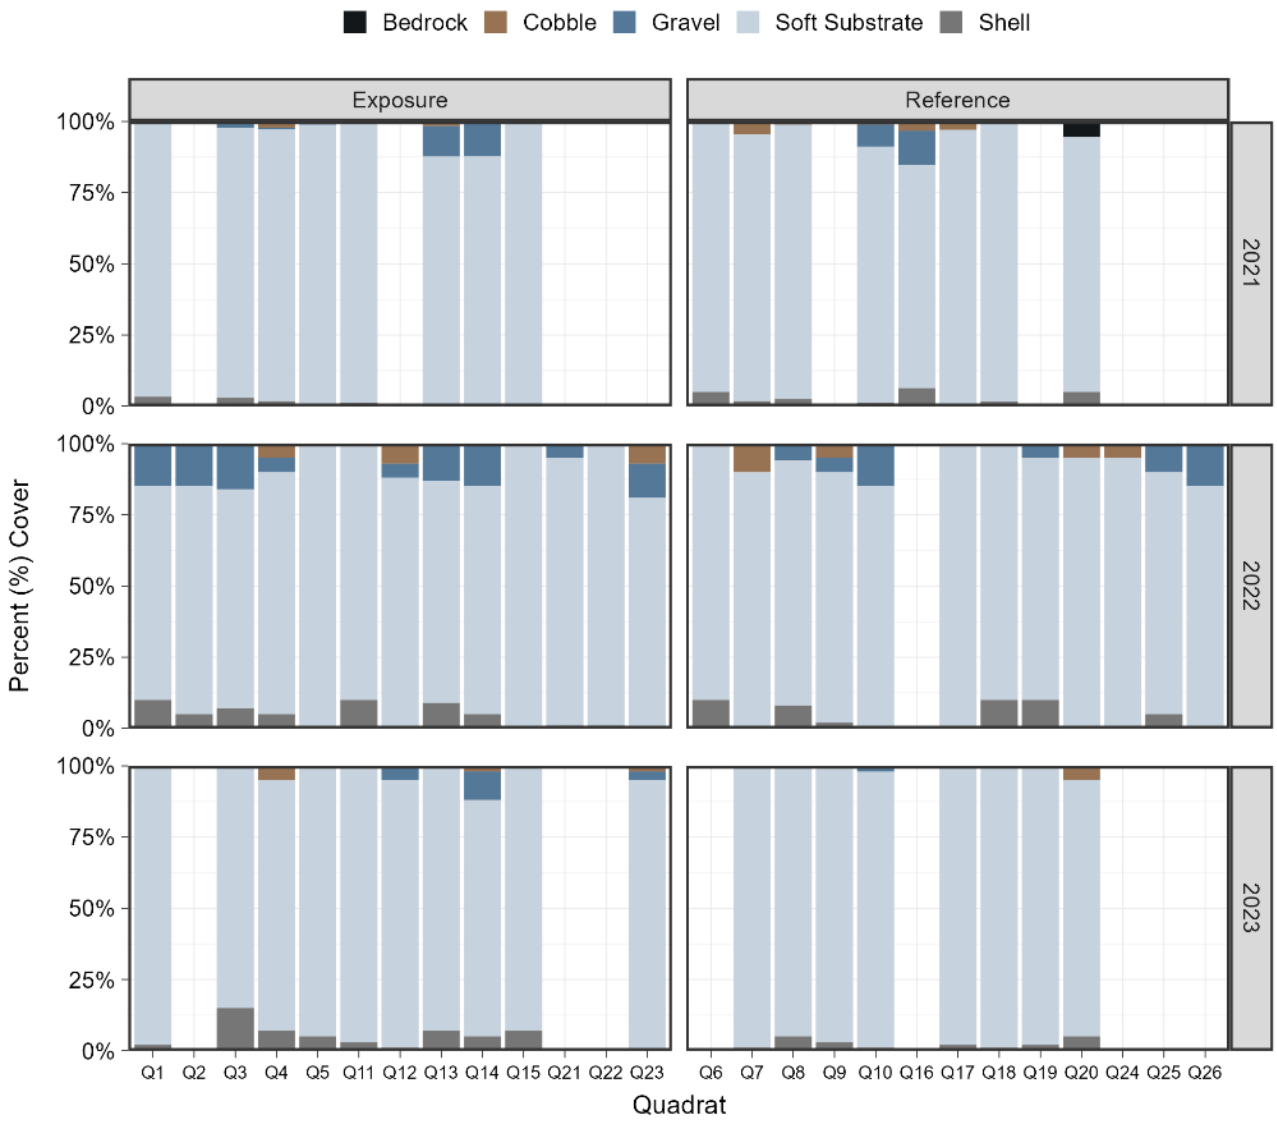
For soft substrate, cover varied significantly among sampling years (P=0.002): mean soft substrate percent cover was lower in 2022 compared to other years when areas were combined (Table 5-3; Figure 5-5). The effect of area (P=0.8) was not significant, indicating no differences in mean soft substrate cover among areas when years were combined. The area × year interaction (P=0.1) was not significant. The non-significant interaction suggests that interannual differences in soft substrate cover did not differ between the reference and exposure areas.

Estimated marginal means were used to describe the magnitude of the differences (i.e., effect sizes) among sampling years (Table 5-4). Within Milne Port, mean soft substrate cover was significantly greater in 2022 compared to 2021 (119%), with no other interannual differences observed. Within the reference area, mean soft substrate cover was significantly lower in 2023 compared to 2022 (-53%), with no other significant interannual differences observed. Effect sizes ranged from -35% to 119% in Milne Port, -53% to 32% in the Reference Area, and was equal to -34% in 2023 between Milne Port and the reference area (Table 5-4).

In the analysis of soft substrate, statistical power was sufficient to detect a significant year and area interaction at effect sizes of -50% and +162% (Appendix 5E). That is, when the 2023 exposure area had mean soft substrate content that was 50% lower or 162% higher than the 2023 reference area, the model could detect a significant interaction between year and area. There was not sufficient power to detect the interaction given the 2023 effect size. The model had higher power to detect decreases than increases in soft substrate, due to the high values of soft substrate observed in 2023 and the bounding of the variable by 0% and 100%.

Other substrate types present in small proportions within each area in 2023 included gravel (0 to 10%), cobble (0 to 5%), and shell (0 to 15%) (Figure 5-3B and C; Figure 5-4). Consistent with 2022 results, bedrock was not observed within the quadrats in 2023 as the limited amount visible in 2021 (only present in one quadrat) had apparently been covered with deposition of finer sediment.





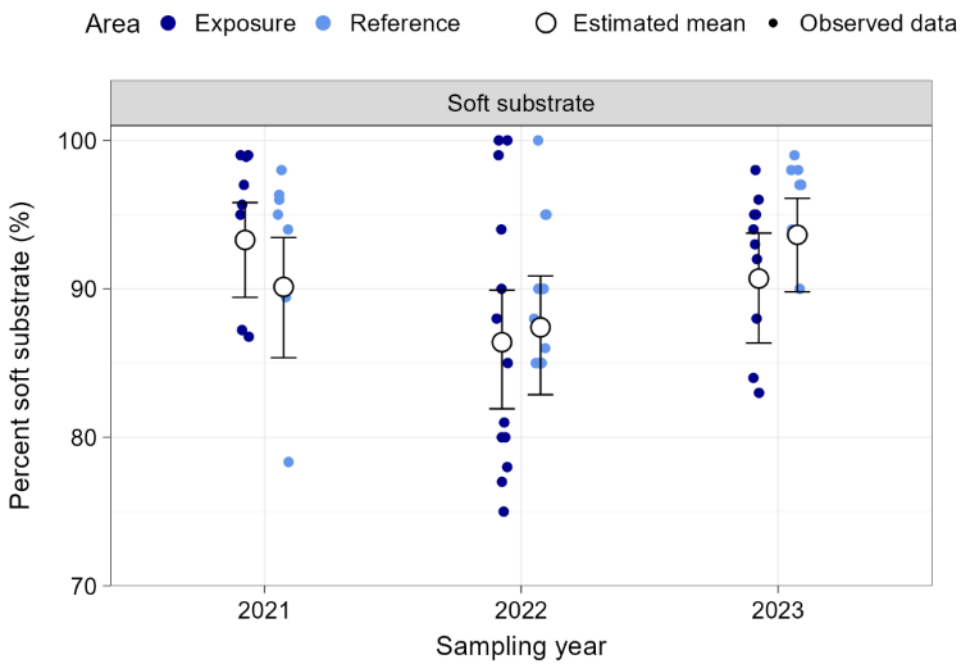


Figure 5-3: Substrate Types Observed in Survey Quadrats at Milne Port, Showing Areas Dominated By: A) Soft Substrate (Sand/Silt); B) Gravel; C) Cobble; and D) Anthropogenic Debris (e.g., chain and rust).

Dashed lines represent the mean percent cover for the exposure and reference quadrats for each year and stars represent years in which individual quadrats were not sampled.

Figure 5-4: Relative Abundance of Substrate Types from Quadrats Surveyed Every Year during Quadrat Surveys in Milne Port, 2021 – 2023.

Soft substrate includes sand and silt. Observed (solid points) and estimated marginal mean percent cover (open points) and 95% confidence interval (error bars) are presented for each sampling area and year.

Figure 5-5: Interannual Differences in Soft Substrate Percent Cover in Milne Port, 2021 – 2023.

Table 5-3: Results of Generalized Linear Mixed Models for Substrate, Macroflora, and Benthic Epifauna in Milne Port, 2021 – 2023

Indicator	Variable	Chi square	DF	P-value

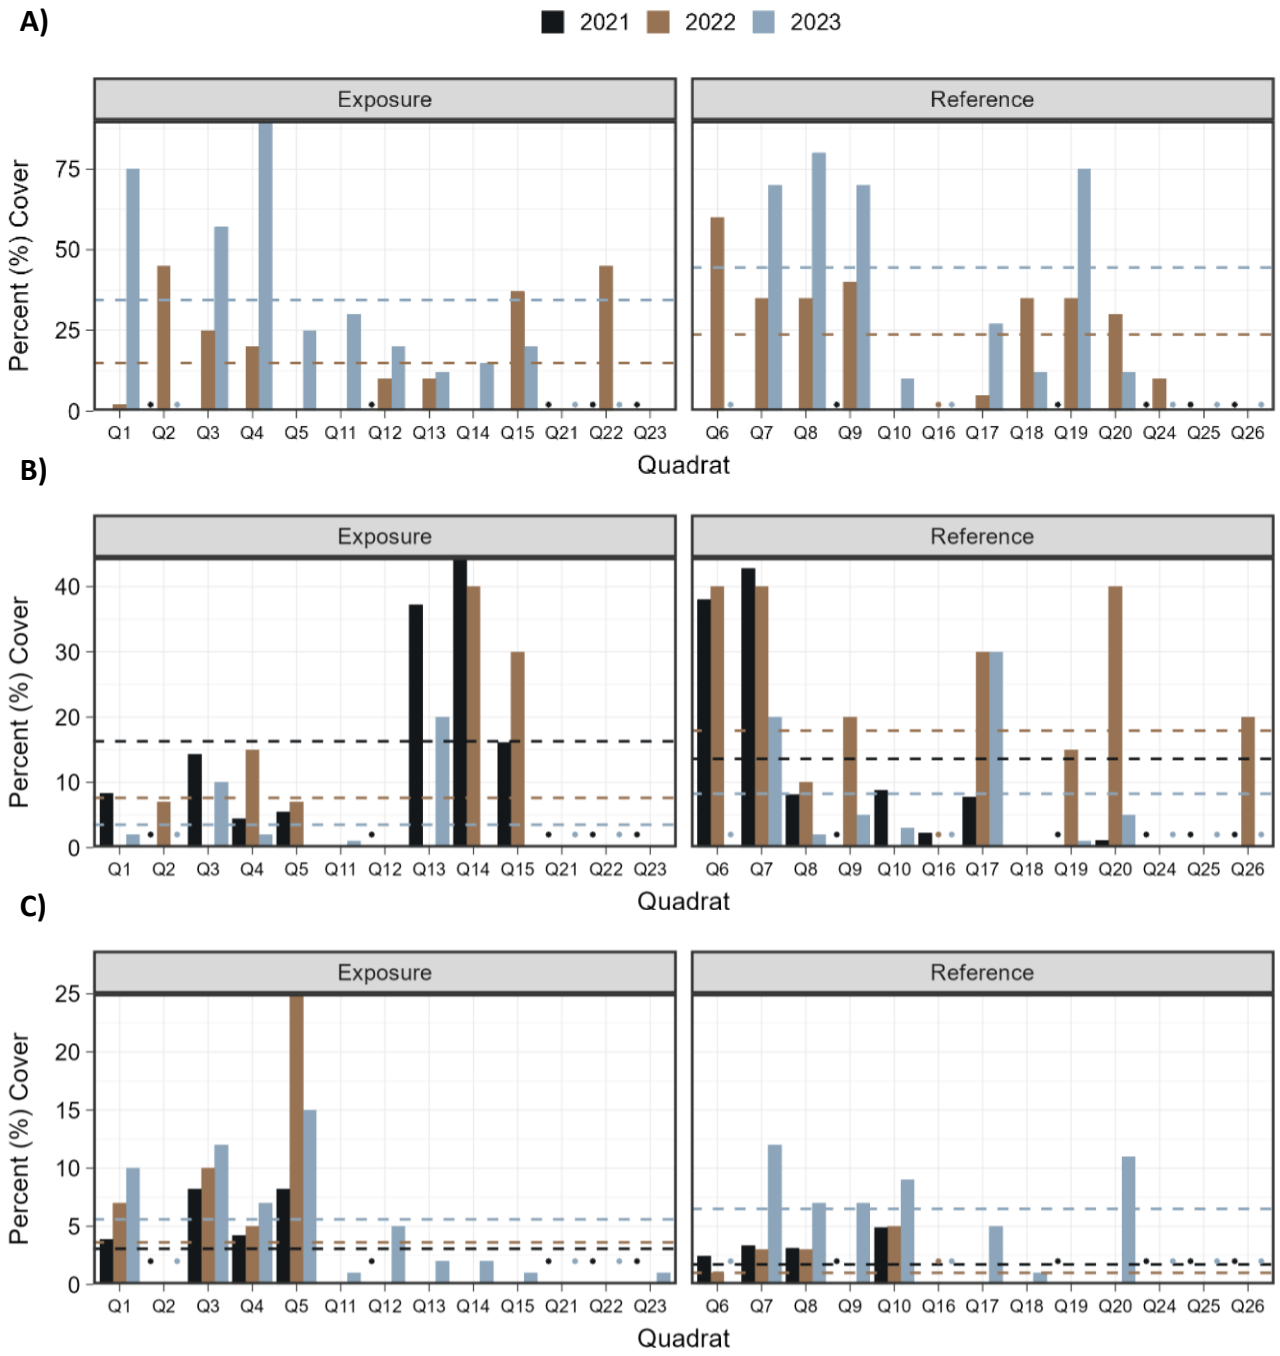
Note: Values are shown as: *P*-value (Effect Size, %). Cells highlighted **blue** indicate statistically significant results (p-value <0.05). Pairwise comparisons were conducted for (1) between years within quadrats and (2) between areas within a year, to describe effect sizes



Detritus and Debris

A detrital veneer was present in most quadrats in 2023, consistent with 2022 results (Figure 5-6A). Unlike in 2022, the exposure area contained a larger range of detrital veneer percent cover compared to the reference area (0 to 90% vs 10 to 80%, respectively).

Detrital (or drift) macroalgae was present in two-thirds of the quadrats (Figure 5-6B), with the reference area having a higher average percent cover of detrital algae compared to the exposure area (consistent with 2022 and 2021 results). Highest percent cover was recorded in Q7, Q13, and Q17 (with 20%, 20%, and 30%, respectively). Overall, the percent detrital algae decreased in 2023 compared to the previous years.

Other debris consisted of rusting metal pieces (Figure 5-3D) from the suspended anchor chain maintaining the NIS/AIS monitoring settlement plate (Chapter 8.0) above the 2020-deployed quadrats (Q1 through Q10)[13], aluminum piping from the belt transects observed in Q5 that has been observed every survey year since 2020, and a piece of white plastic debris noted in Q3 in 2023 (Figure 5-6C).

[13] Quadrats deployed in later years did not use chain as part of the experimental design.

Dashed lines represent the mean percent cover for the exposure and reference quadrats for each year and stars represent years in which individual quadrats were not sampled.

Figure 5-6: A) Total Percent Cover of Detrital Veneer, B) Detrital Macroalgae, and C) Other Anthropogenic Debris from Quadrats Surveyed during Quadrat Surveys in Milne Port, 2021 – 2023.

5.4.2 Macroflora

Macroflora identified in quadrats belonged to four larger taxonomic groups: Ochrophyta (brown algae), Rhodophyta (red algae), Chlorophyceae (green algae), and Bryophyta (Appendix 5C). There were no new taxa discovered in 2023 and there were no opportunistic collections of unfamiliar specimens to send to taxonomic laboratories for identification.

Brown algae were resolved to four distinct taxa in 2023, two of which were defined to species level: sugar kelp (*Saccharina latissima*), and rockweed (*Fucus distichus)* (Appendix 5B – Photos 2 to 4). The other two brown algae were identified to genus level - *Pylaiella* sp., and acid weed (*Desmarestia* sp.) (Appendix 5B – Photos 4 to 6). Red algae observed within the quadrats that could be identified to the species level were *Coccotylus truncatus* and *Savoiea arctica* (Appendix 5B – Photos 6 and 7). Other red algae observed included encrusting coralline algae (Corallinales indet.) and unidentified filamentous and branched algae (Appendix 5B – Photo 8). Green algae comprised one species, *Chaetomorpha melagonium* (Appendix 5B – Photos 3 and 4), while others were unidentified filamentous green algae. Eight macroalgae taxa observed in previous years (2021 and 2022) were not observed in 2023, including sieve kelp (*Agarum clathratum*), brown filamentous algae *Halosiphon tomentosus* and *Coelocladia arctica*, and red foliose *Dilsea socialis* (Appendix 5C; Golder 2022; WSP 2023).

Percent Cover

Macroalgae percent cover varied greatly among quadrats (from 5 to 100%) in both the exposure and reference areas (Figure 5-7). Q13 in the exposure area had the highest percent cover (83%) while the other quadrats in the exposure area were all below 50%. Half of the quadrats surveyed within the reference area in 2023 contained coverage greater than 50%, resulting in a higher average percent cover compared to the exposure area. Exposure area percent cover in 2023 was equivalent to 2022 and higher than in 2021 (2023 = 23.8%; 2022 = 23.9%; 2021 = 17.8%), but the percent cover in the reference area shows a trend of increasing cover from 18.2% in 2021 to 50.8% in 2023 (Table 5-5).

When investigating differences in macroalgae cover between sampling areas and among years, the interaction between area and year was significant (P=0.017), indicating differing trends in interannual differences among sampling areas (Table 5-3). Within Milne Port, percent cover of macroalga did not differ significantly among sampling years (Table 5-4). In contrast, within the reference area, percent cover of macroalga differed significantly among sampling years (Table 5-4): mean macroalgae percent cover was highest in 2021, differing significantly from 2022 (-78%) and 2023 (-88%), which did not differ from each other. Effect sizes ranged from -45% to 5% in Milne Port, -88% to -45% in the reference area, and was equal to -69% in 2023 between Milne Port and the reference area (Table 5-4).

In the analysis of macroalgal percent cover, statistical power did not have sufficient power to detect a significant interaction at any of the examined effect sizes, ranging from -90% to +400% (Appendix 5E). There was not sufficient power to detect the observed effect size between Milne Port and the reference area. The low statistical power was likely due to the high variability in percent cover of macroflora, leading to high uncertainty and lack of statistical significance.

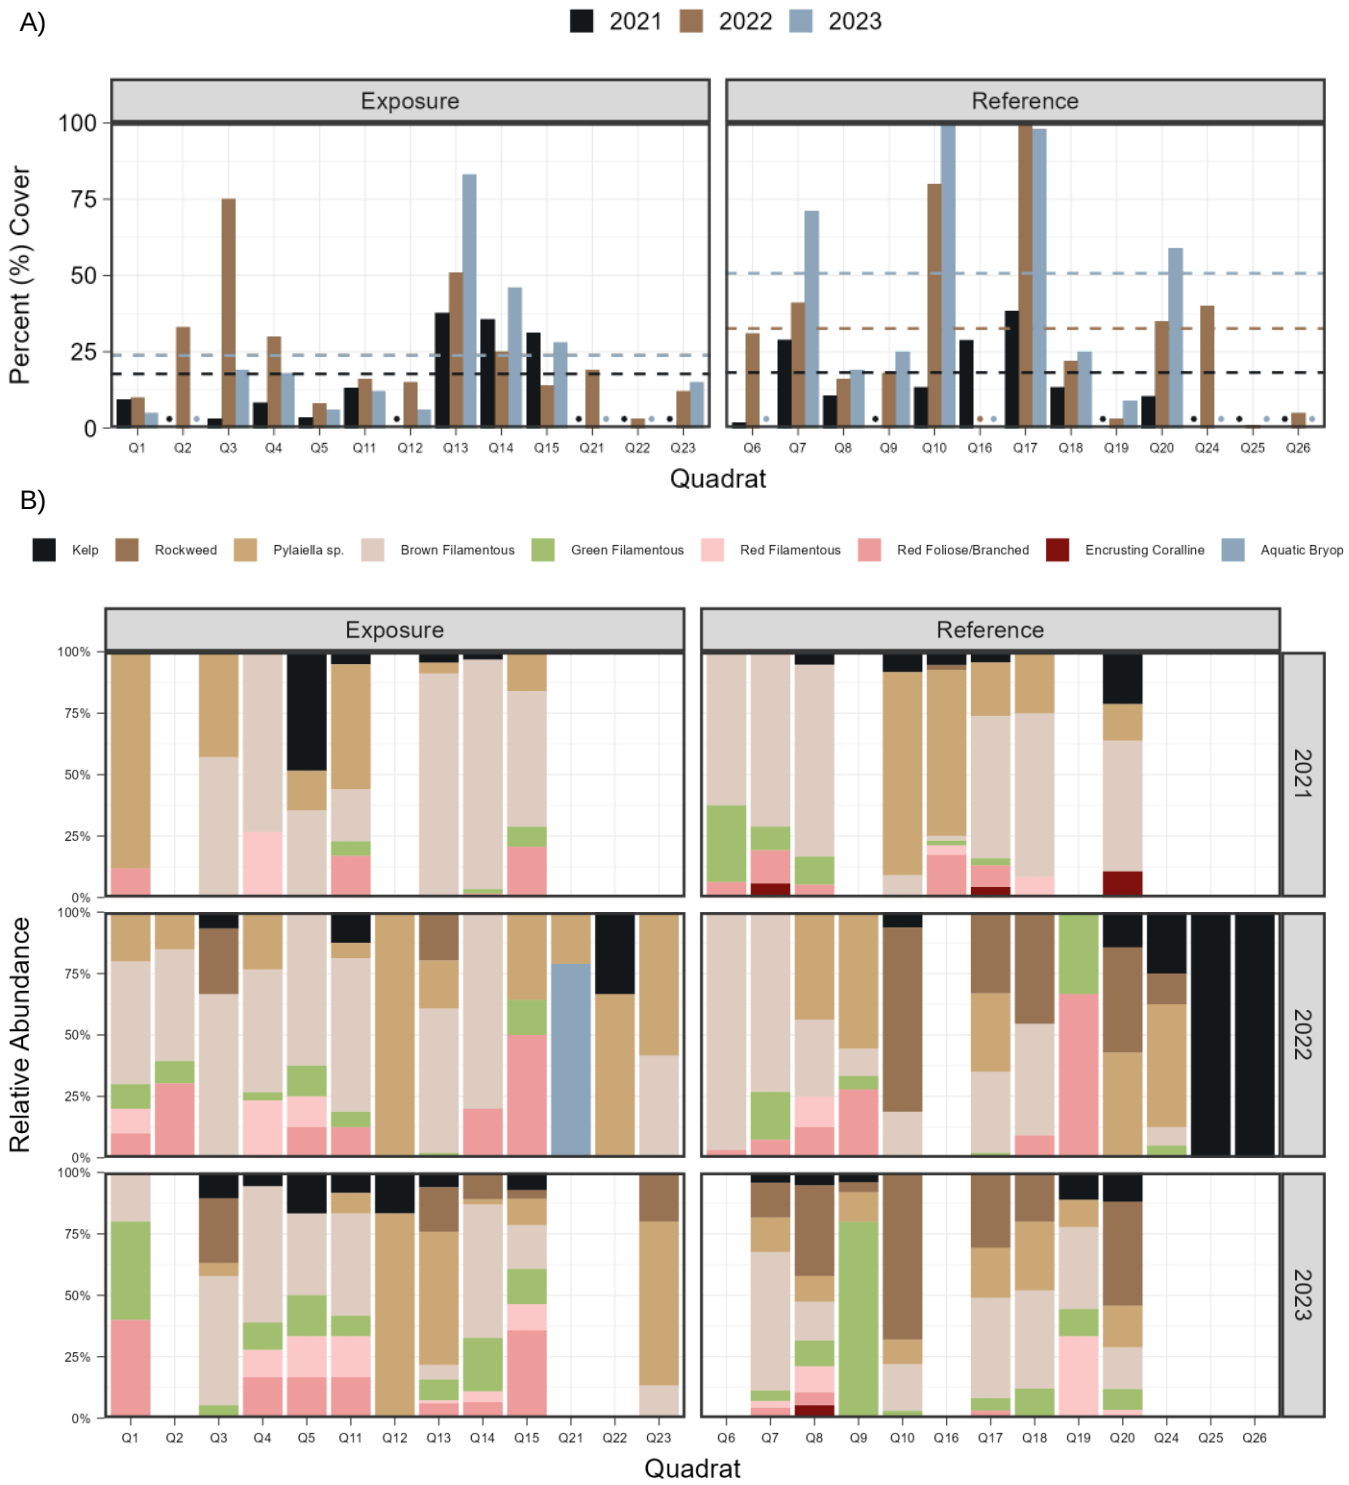
The most abundant macroalgae type in 2023 was brown algae (acid weed and rockweed) and ephemeral *Pylaiella* sp. across both areas (Table 5-5; Figure 5-7). Sugar kelp, *C. melagonium*, and *C. truncatus* were also present in lower proportions in several quadrats in both areas. Overall, relative abundance of major algae classifications was comparable between years; however, *Pylaiella* sp. appeared to decrease in abundance in 2022 and 2023 compared to 2021 and rockweed and green filamentous algae appeared to increase in abundance since 2021 (Figure 5-7).

Diversity

Macroalgae diversity (taxa richness and SDI) was similar between the exposure and reference area in 2023. Taxa richness ranged between three to seven taxa in the exposure area and four to eight taxa in the reference area, and SDI ranged from low (0.250-0.499) to high (>0.750) in both areas (Table 5-5; Figure 5-9A). Both taxa richness and SDI means and ranges were higher for their respective areas in 2023 compared to both previous years (Figure 5-9B; Golder 2022; WSP 2023).

Macroalgal taxa richness differed significantly between sampling years (*P*=0.002; Figure 5-7) but did not differ among sampling areas (P=0.60; Table 5-3). In addition, the interaction between area × year was also not significant (*P*=0.7), indicating annual differences in macroflora richness were not different between the reference and exposure areas (Table 5-3). *Post hoc* comparisons indicated that macroalgal taxa richness was significantly lower in 2023 compared to 2022 (-48%) in the reference area: no other significant differences were observed (Table 5-4). Effect sizes ranged from -36% to 27% in Milne Port, -48% to 59% in the reference area, and was equal to -13% in 2023 between Milne Port and the reference area (Table 5-4).

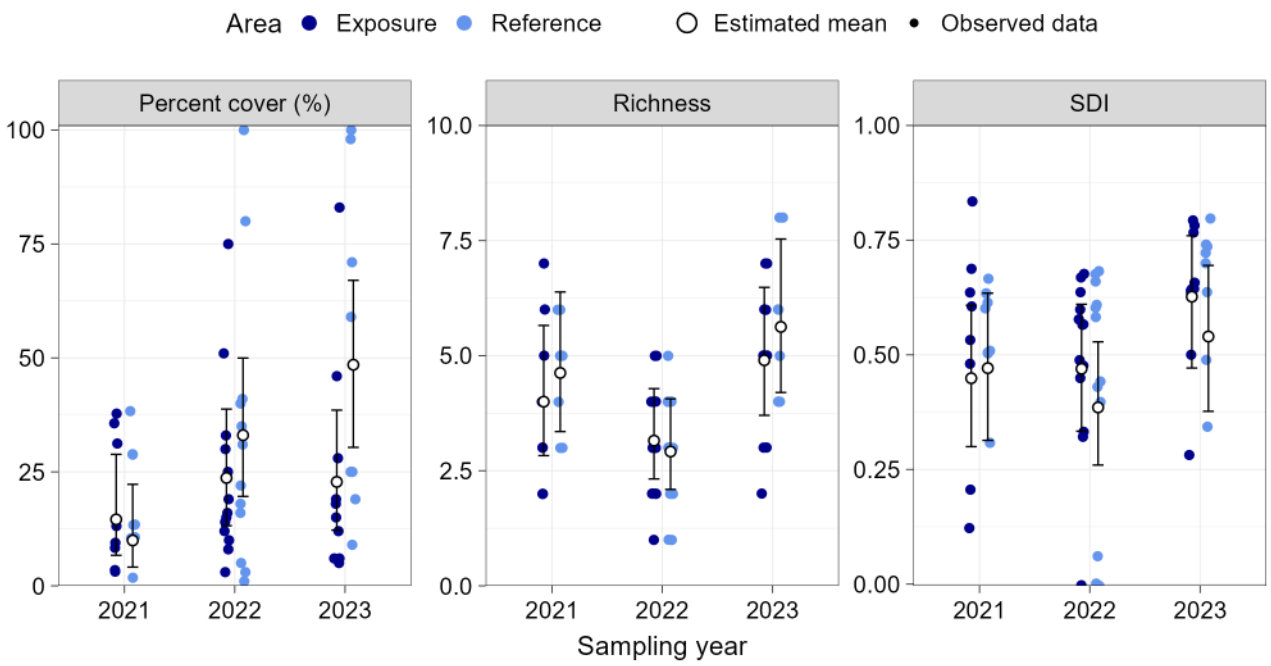
In the analysis of macroalgal species richness, statistical power was sufficient to detect a significant year and area interaction at effect sizes of -62% and +102% (Appendix 5E). That is, when the 2023 exposure area had mean macroflora richness 62% lower or 102% higher than the 2023 reference area, the model could detect a significant interaction between year and area. The observed effect size was small (-13%), and hence power to detect it was low.



Similarly, macroalgae SDI differed significantly among sampling years (*P*=0.003; Figure 5-8) but did not differ between sampling areas (*P*=0.50); the interaction between area and year was also not significant (*P*=0.50; Table 5-3). Within Milne Port, macroalgae SDI was significantly lower in 2023 compared with 2021 (-51%) and 2022 (-47%), which did not differ from each other. Within the reference area, no significant interannual differences were observed (Table 5-4). Effect sizes ranged from -51% to -7.9% in Milne Port, -47% to 42% in the reference area, and was 43% in 2023 between Milne Port and the reference area (Table 5-4).

In the analysis of macroalgal SDI, statistical power was sufficient to detect a significant year and area interaction at an effect size of +312%, but not at any of the negative effect sizes (Appendix 5E). The observed effect size in 2023 was +43%, and statistical power to detect it was low (<0.3), likely due to the high variability associated with the data.

Table 5-5: Quadrat Survey Results for Macroflora in Milne Port (2023)



Survey Area	Quadrat	Macroalgae			
		Total Cover (%)	Taxa Richness	SDI	Dominant Taxa
Milne Port (Exposure)	Q1	5	3	0.640	*Coccotylus truncatus, Chaetomorpha melagonium*

Dashed lines represent the mean percent cover for the exposure and reference quadrats for each year and stars represent years in which individual quadrats were not sampled.

Figure 5-9: A) Taxa Richness and B) Simpson's Diversity Index of Macroflora Recorded in Quadrats Surveyed During Quadrat Surveys in Milne Port, 2021 – 2023.

5.4.3 Benthic Epifauna

Benthic epifauna identified in the quadrats in 2023 belonged to six phyla: Annelida, Arthropoda, Cnidaria, Chordata, Echinodermata, and Mollusca. One new species, a nudibranch, was collected and identified by the taxonomy laboratory as *Dendronotus* sp.[14] (Appendix 5B – Photo 9).

The majority of species identified in the quadrats belonged to the phylum Mollusca, with four taxa identified to species level: wrinkled rock-borer clam (*Hiatella arctica*), blunt gaper clam (*Mya truncata*), Icelandic scallop (*Chlamys islandica*), and discord mussel (*Musculus discors*) (Appendix 5B – Photos 7, 9, and 10). Other unique molluscs included *Dendronotus* nudibranch, margarite snail (*Margarites* sp.), astarte clam (*Astarte* sp.), whelk (Family Buccinidae) (Appendix 5B – Photo 11), and limpet (Subclass Patellogastropoda). Phylum Annelida was represented by three distinct taxa: cone worm (*Cistenides granulata*) (Appendix 5B – Photo 11) and two morphologically distinct sabellid polychaetes (Family Sabellidae)[15] (Appendix 5B – Photos 4 and 12). Phylum Arthropoda (subphylum Crustacea) was represented by amphipods, shrimp of the superfamily Pandaloidea and a single crangon shrimp (Family Crangonidae) (Appendix 5B – Photos 13 and 14). The phylum Echinodermata included brittle stars (Class Ophiuroidea), green urchin (*Strongylocentrotus droebachiensis*), and six-rayed sea star (*Leptasterias* sp.) (Appendix 5B – Photos 15 to 17) and the phylum Cnidaria was represented by a single burrowing anemone (Subclass Ceriantharia) (Appendix 5B – Photo 18). Phylum Chordata included one species of tunicate (*Polycarpa* sp.), and fish from the sculpin family (Family Cottidae; one species), Saddled Eelpout (*Lycodes mucosus*), and juvenile Common Lumpfish (*Cyclopterus lumpus*) (Appendix 5B – Photos 8 and 19).

5.4.3.1 Sessile Epifauna

Wrinkled rock-borer clams (one of the species used for fish health monitoring at Milne Inlet; Chapter 7.0), and cone worms were the dominant sessile epifauna taxa in the majority of quadrats in both areas in 2023, consistent with results from previous years (Table 5-6; Figure 5-10). Blunt gaper clams and sabellid worms were also frequently observed in quadrats in both areas. Two sessile epifaunal taxa observed in previous years (2021 and 2022) were not observed in 2023: scallop *Similipecten greenlandicus* and northern astarte clam *A. borealis* (Appendix 5C; Golder 2022; WSP 2023).

Percent Cover

Total percent cover of sessile epifauna varied among quadrats in both exposure and reference areas but on average was slightly higher in the reference area than in the exposure area (25.5 ± 5.7% and 40.8 ± 6.4%, respectively) (Table 5-6; Figure 5-10). Total percent cover of sessile epifauna was lowest in Q23 within the exposure area with 1% cover (exclusively from small sabellid worm sp. 1), a minor increase from no sessile epifauna observed in the first year of sampling in 2022 (Appendix 5C). The highest percent cover was recorded in Q1 within the exposure area (62%) and Q20 within the reference area (71%; Table 5-6).

For sessile percent cover, the model that included the effect of depth as a covariate was the best supported based on AIC and was selected for interpretation. Percent cover of sessile epifauna varied significantly with depth (P=0.019) but did not differ among sampling years (P=0.050); the area × year interaction (P=0.1) was not significant (Table 5-3). Post hoc comparisons indicated few significant differences (Table 5-4). Within Milne Port,

[14] Possibly *Dendronotus arcticus*, though similar to D. *robustus* or D. *frondosus*.

[15] A large tube casing collected in 2022 was identified by the laboratory as *Pista maculata* (Family Terebellidae); however, since this organism was not observed to be alive in the field, it is not completely linked to the Large sabellid worm sp. 2 that has been observed in all years 2021 to 2023.

no post hoc differences were observed. Within the reference area, mean sessile percent cover was significantly lower in 2023 compared to 2022 (-65%). No other significant differences were observed (Table 5-4). Effect sizes ranged from -40% to 25% in Milne Port, -65% to -24% in the reference area, and was equal to -27% in 2023 between Milne Port and the reference area (Table 5-4; Figure 5-11).

In the analysis of sessile epifauna percent cover, statistical power was not sufficient power at any of the examined effect sizes, ranging from -90% to +400% (Appendix 5E), likely due to the high variability associated with the data (Figure 5-11). The observed effect size in 2023 was -27%, and statistical power to detect the effect was low.

Relative abundance of sessile epifauna also varied between the quadrats but remained within the same ranges between the exposure and reference areas in 2023, as well as being comparable to previous years (2021 and 2022) (Figure 5-10; Appendix 5C). Sabellid worm percent cover increased in 2023 compared to previous years while scallop and clam abundance decreased (Figure 5-10).

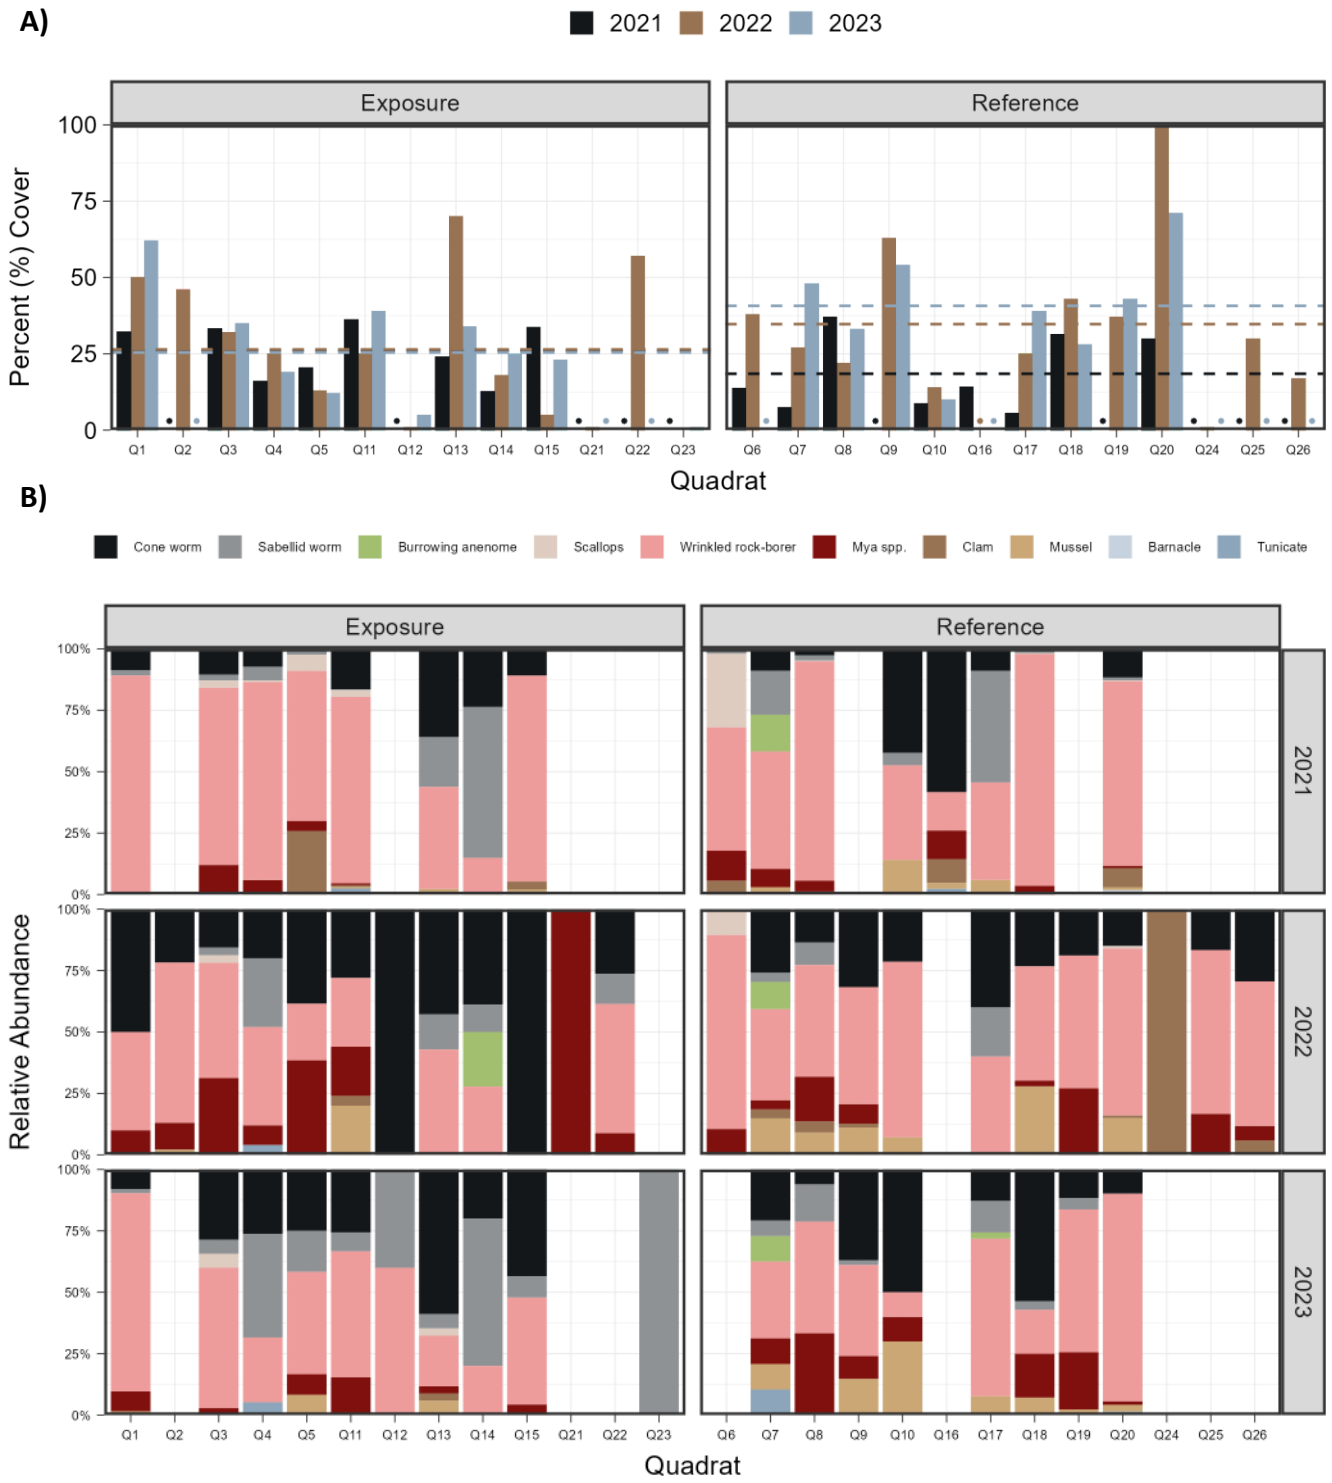
Diversity

Mean taxa richness was similar between the exposure area (4.5 ± 0.6 taxa) and reference area (5.6 ± 0.5 taxa) in 2023 (Figure 5-12), with mean taxa richness comparable to 2022 in the exposure area but slightly lower within the reference area compared to 2022; both areas had greater mean taxa richness compared to 2021 (Table 5-6; Figure 5-12). The highest number of taxa was observed in Q7 within the reference area (nine taxa) and Q13 within the exposure area (eight taxa), with both quadrats seeing an increase in taxa richness from 2022 (seven and three taxa, respectively) and 2021 (seven and four taxa, respectively; Appendix 5C).

For sessile richness, the model that included a non-linear effect of depth as a covariate was the best supported based on AIC and was selected for interpretation. Sessile taxa richness varied significantly with depth (P=0.04) and among sampling years (P<0.001) but did not differ between samplings areas (P=0.1); the area × year interaction (P=0.9) was not significant (Table 5-3). Estimated marginal means comparisons indicated sessile taxa richness was significantly greater in 2022 compared to 2021 in both the Milne Port and reference area (75% and 81%, respectively). No other significant differences were observed (Table 5-4). Effect sizes ranged from -40% to 75% in Milne Port, -35% to 81% in the reference area, and was equal to -11% in 2023 between Milne Port and the reference area (Table 5-4; Figure 5-11).

In the analysis of sessile epifauna richness, there was sufficient statistical power to detect a significant interaction at effect sizes of -72% and +71% (Appendix 5E). That is, when the 2023 Milne Port area had mean sessile epifauna richness 72% lower or 71% higher than the 2023 reference area, the model could detect a significant interaction between year and area. The observed effect size in 2023 was small (-12%; Figure 5-11).

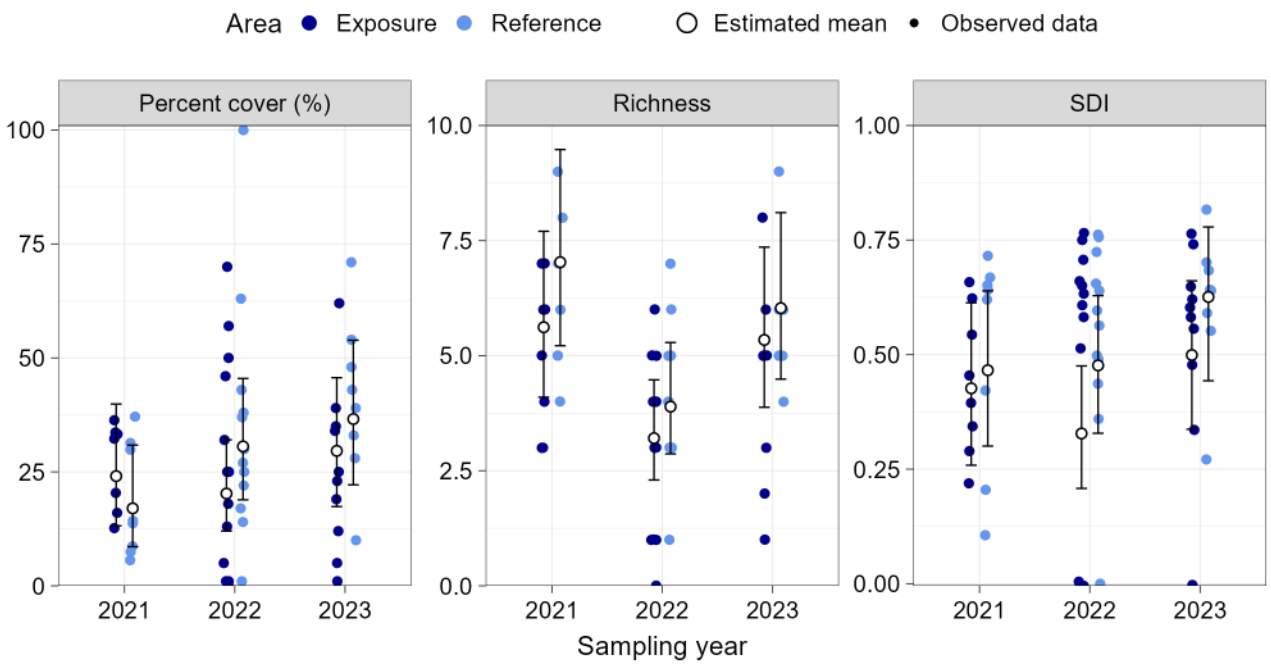
Values of SDI ranged from very low (<0.250) to high (>0.750) in the exposure area and from low (0.250-0.499) to high (>0.750) in the reference area (Figure 5-12), with only minor differences in mean values between areas (exposure = 0.533±0.071; reference = 0.613±0.056) (Table 5-6). SDI was very low (0.000) for Q23 due to very low abundance of only one taxon but high in Q4 within the exposure area and Q7 within the reference area due to even abundance of observed taxa (Table 5-6; Appendix 5C).



For sessile SDI, the model that included the effect of soft substrate as a covariate was the best supported based on AIC and was selected for interpretation. Sessile SDI varied significantly with soft substrate (P=0.005) but did not differ among sampling years (P=0.06), between sampling area (P=0.2), or the area × year interaction (P=0.7; Table 5-3). Effect sizes ranged from -51% to 52% in Milne Port, -48% to -4.1% in the reference area, and was equal to -40% in 2023 between Milne Port and the reference area (Table 5-4; Figure 5-11).

In the analysis of sessile epifauna SDI, there was sufficient statistical power to detect a significant interaction at an effect size of +213%, but not at any of the examined negative effect sizes, ranging up to -90% (Appendix 5E). The observed effect size in 2023 was -40%, and statistical power to detect the effect was low (<0.3).

Table 5-6: Quadrat Survey Results for Sessile Epifauna in Milne Port (2023)



Survey Area	Quadrat	Sessile Epifauna			
		Total Cover (%)	Taxa Richness	SDI	Dominant Taxa

Figure 5-12: A) Taxa Richness and B) Simpson's Diversity Index of Sessile Epifauna Recorded in Quadrats Surveyed During Quadrat Surveys in Milne Port, 2021 – 2023.

5.4.3.2 Motile Epifauna

Nudibranchs were the dominant motile epifauna taxa observed in quadrats in both areas in 2023, followed by shrimp and green urchins in the exposure area and Saddled Eelpouts in the reference area (Figure 5-13; Appendix 5C). Brittle stars and green urchins that were observed at high densities in 2022 and 2021 were rarely observed in 2023 (Figure 5-13); the low densities of brittle stars and green urchins may be due to not sampling quadrats that in previous years have had high densities of these taxa (e.g., Q2, Q6, Q22) or interannual variability such as the late ice cover observed in 2023 (Appendix 5C). Several taxa were observed for the first-time during surveys, including a Buccinidae whelk (previously seen in ROV surveys in 2020) and six-rayed sea stars (a genus recorded during benthic sampling [Chapter 4.0] in 2021 and 2022) (Appendix 5C). Seven motile epifauna taxa observed in previous years (2021 and/or 2022) were not observed in 2023, including polychaetes, ribbon worms (Phylum Nemertea), sea cucumbers (Family Holothuroidea), and Fish Doctor (*Gymnelus viridis*) (Appendix 5C; Golder 2022; WSP 2023).

Density

Motile epifauna density was lower in 2023 than in 2022 and 2021 in both areas (Table 5-7). Within the exposure area, mean density decreased to 7.6 ± 1.5 org/m^2 from 12.4 ± 4.4 org/m^2 in 2022 and 16.0 ± 6.2 org/m^2 in 2021 (Table 5-7; Figure 5-13; Appendix 5C). The reference area consistently showed greater variability in mean density but also decreased to 6.9 ± 2.0 org/m^2 from 12.5 ± 9.3 org/m^2 in 2022 and 28.1.0 ± 18.5 org/m^2 in 2021 (Table 5-7; Appendix 5C). Six quadrats (Q4, Q5, Q13, Q15, Q18, and Q18) contained motile epifauna densities greater than 10 org/m^2 and only one quadrat (Q23) contained no motile epifauna (Table 5-7). Most quadrats contained a single organism from two to three taxa (Appendix 5C).

For motile epifauna density, the model that included the effect of depth as a covariate was the best supported based on AIC and was selected for interpretation. Motile density varied significantly with depth (P<0.001), and the area × year interaction (P=0.001) was statistically significant (Table 5-3). A significant interaction indicates that the relationship between year and motile density varied by sampling area. Within Milne Port, motile epifaunal density was significantly higher in 2023 compared to 2021 (80%) but was not different among other sampling years (Table 5-4). Within the reference area, epifaunal density was significantly higher in 2022 compared to 2021 (347%) and 2023 (70%) but did not differ among other sampling years (Figure 5-14; Table 5-4). Effect sizes ranged from 22% to 80% in Milne Port, -70% to 347% in the reference area, and was equal to -16% in 2023 between Milne Port and the reference area (Table 5-4; Figure 5-14).

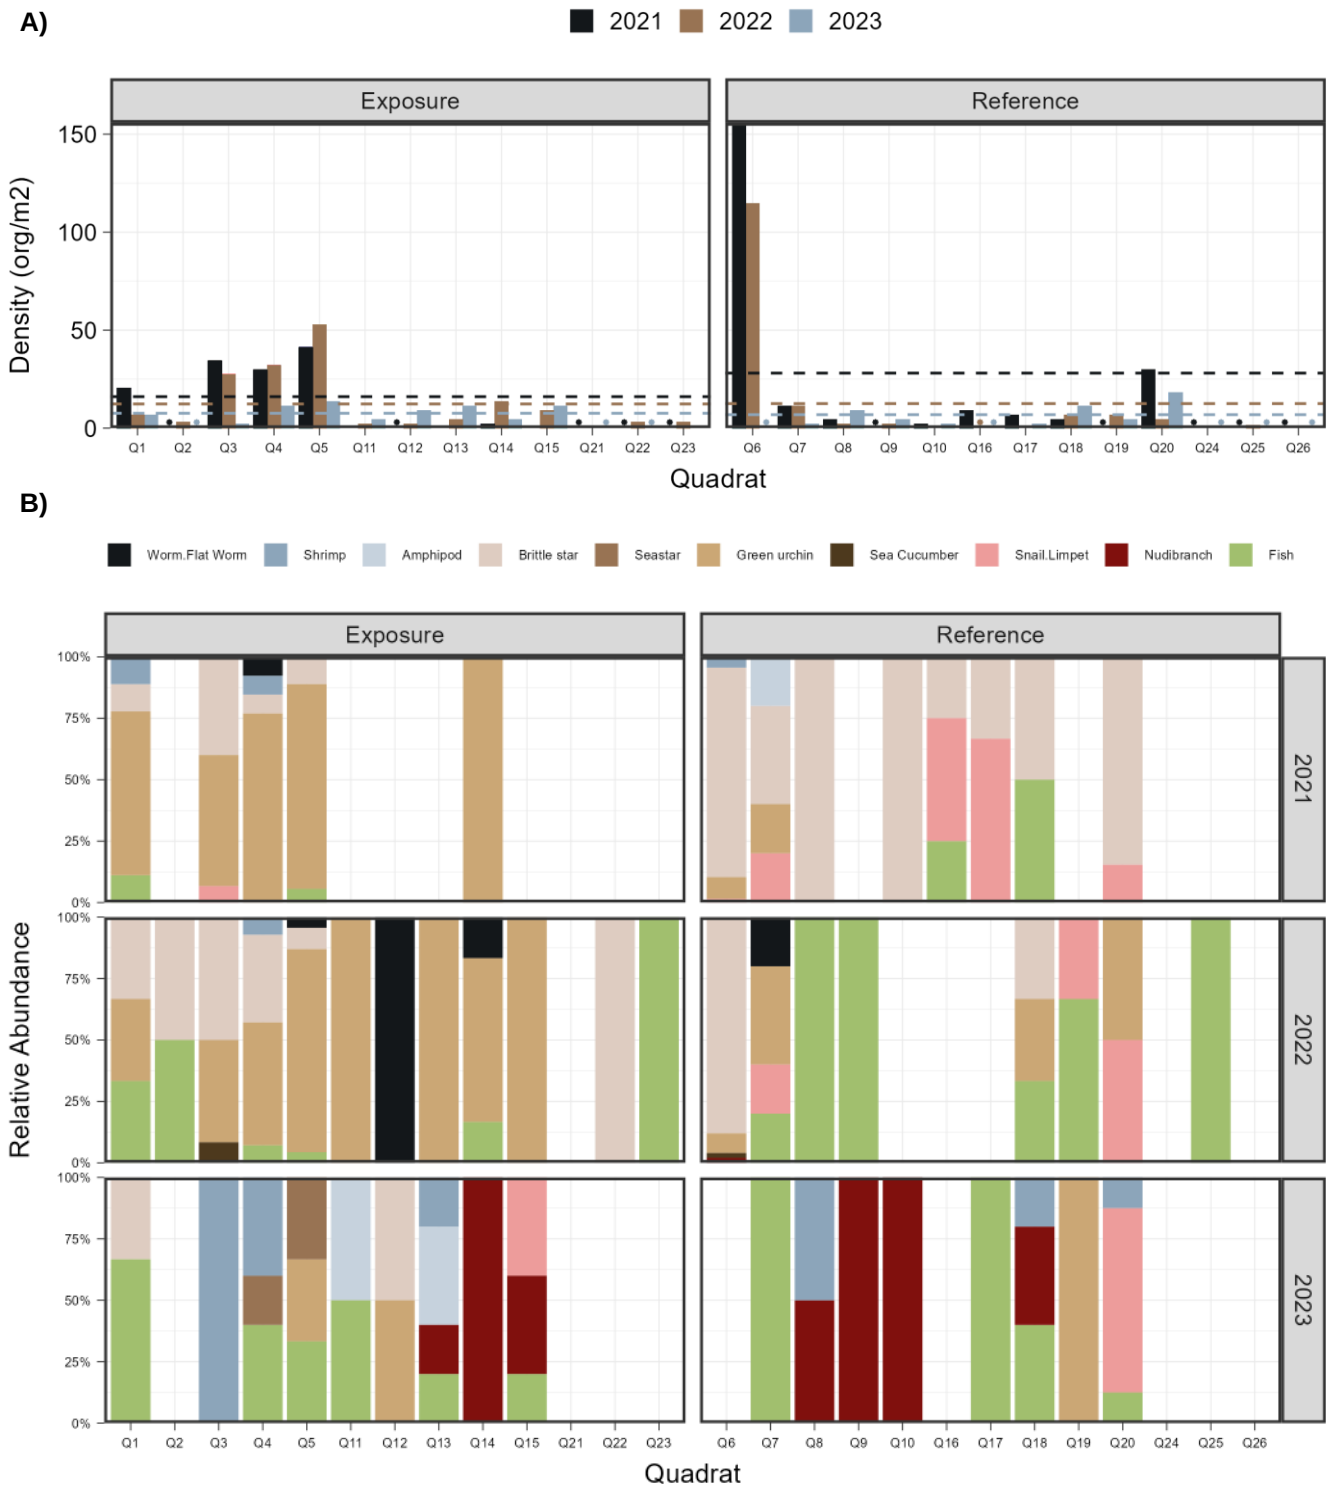
In the analysis of motile epifauna density, there was sufficient power to detect a significant interaction at effect sizes <+30% and >+172% (Appendix 5E). That is, when the 2023 Milne Port area had mean motile epifauna density that was less than 30% higher or more than 172% higher than the 2023 reference area, the model could detect a significant interaction between year and area. The observed effect size in 2023 was -16%, and statistical power to detect the effect was high. The power to detect an interaction was >0.7 for all examined effect sizes, due to the large difference between reference and Milne Port in 2022, but not in 2021 (Figure 5-14), which resulted in a high proportion of simulations with a significant interaction between year and area. The estimated statistical power was at its lowest at effect sizes of approximately 60%–120%, since at those effect sizes, the difference between reference and Milne Port areas in 2023 became similar to the difference between reference and Milne Port areas in 2022 (Figure 5-14), and the statistical significance of the interaction decreased; instead, the main effect of area was significant more often.

Diversity

Diversity (taxa richness and SDI) was low overall for motile epifauna in both areas in 2023. Taxa richness was similar between the two survey areas (ranging 0-4 in both), consistent with previous years (Figure 5-15). SDI values were polarized in both areas in 2023, with exposure area quadrats having either very low (0.000) or moderate (0.500-0.750) SDI, while in the reference area SDI was generally very low (0.000) or high (>0.750) with one moderate site (Q18; SDI = 0.720) (Table 5-7). Seven quadrats (39%) had a SDI of zero; these quadrats either lacked any motile epifauna (Q23) or they contained only one or two organisms of a single taxon (Q3, Q7, Q9, Q10, Q13, Q14, Q17, and Q19) (Table 5-7; Figure 5-15).

For motile taxa richness, the model that included a non-linear effect of depth as a covariate was the best supported based on AIC and was selected for interpretation. Motile taxa richness varied significantly with depth but did not differ among sampling years (P=0.05) or between sampling areas (P=0.50); the area × year interaction (*P*=0.40) was not significant (Table 5-3). Effect sizes ranged from -39% to 17% in Milne Port, -40% to 101% in the reference area, and was equal to 32% in 2023 between Milne Port and the reference area (Table 5-4; Figure 5-14).

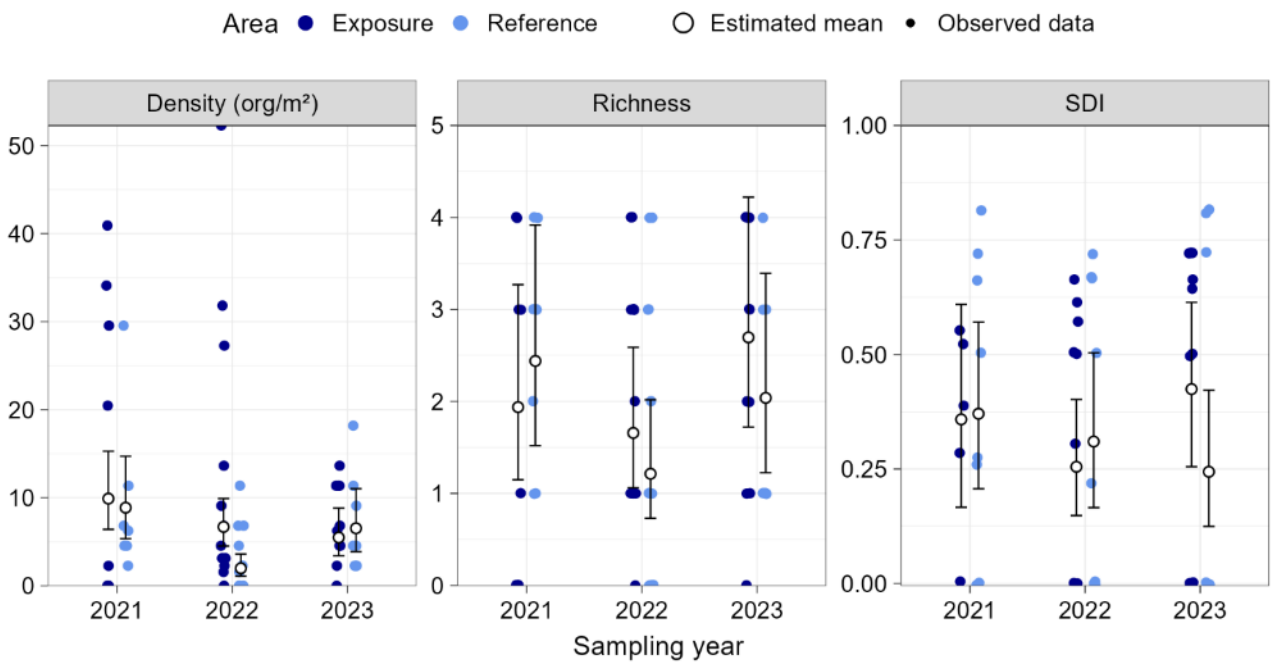
In the analysis of motile epifauna richness, there was sufficient power to detect a significant interaction at an effect size of +220%, but not any of the examined negative effect sizes, up to -90% (Appendix 5E). That is, when the 2023 Milne Port area had mean motile epifauna richness that was 220% higher than the 2023 reference area, the model could detect a significant interaction between year and area. The observed effect size in 2023 was +32% (Figure 5-14), and statistical power to detect the effect was low. The low power to detect decreases in richness was likely due to the variability associated with the observed data (Figure 5-14).



No differences in motile SDI were found between sampling areas (P=0.60), among sampling years (P=0.50), or the area × year interaction (P=0.3; Table 5-3). Some interannual variation was observed in motile SDI (Figure 5-14). Effect sizes ranged from -54% to 63% in Milne Port, 31% to 83% in the reference area, and was equal to 129% in 2023 between Milne Port and the reference area (Table 5-4).

In the analysis of motile epifauna SDI, there was sufficient power to detect a significant interaction at effect sizes of -88%, but not at any of the examined positive effect sizes, up to 400% (Appendix 5E). The observed effect size in 2023 was +129% (Figure 5-14), and statistical power to detect the effect was low. The low power to detect increases in motile epifauna SDI was likely due to the variability associated with the observed data, as well as with the relatively low value of SDI in the reference area in 2023 (Figure 5-14).

Table 5-7: Quadrat Survey Results for Motile Epifauna in Milne Port (2023)



Survey Area	Quadrat	Motile Epifauna			
		Density (org/m^2)	Taxa Richness	SDI	Dominant Taxa

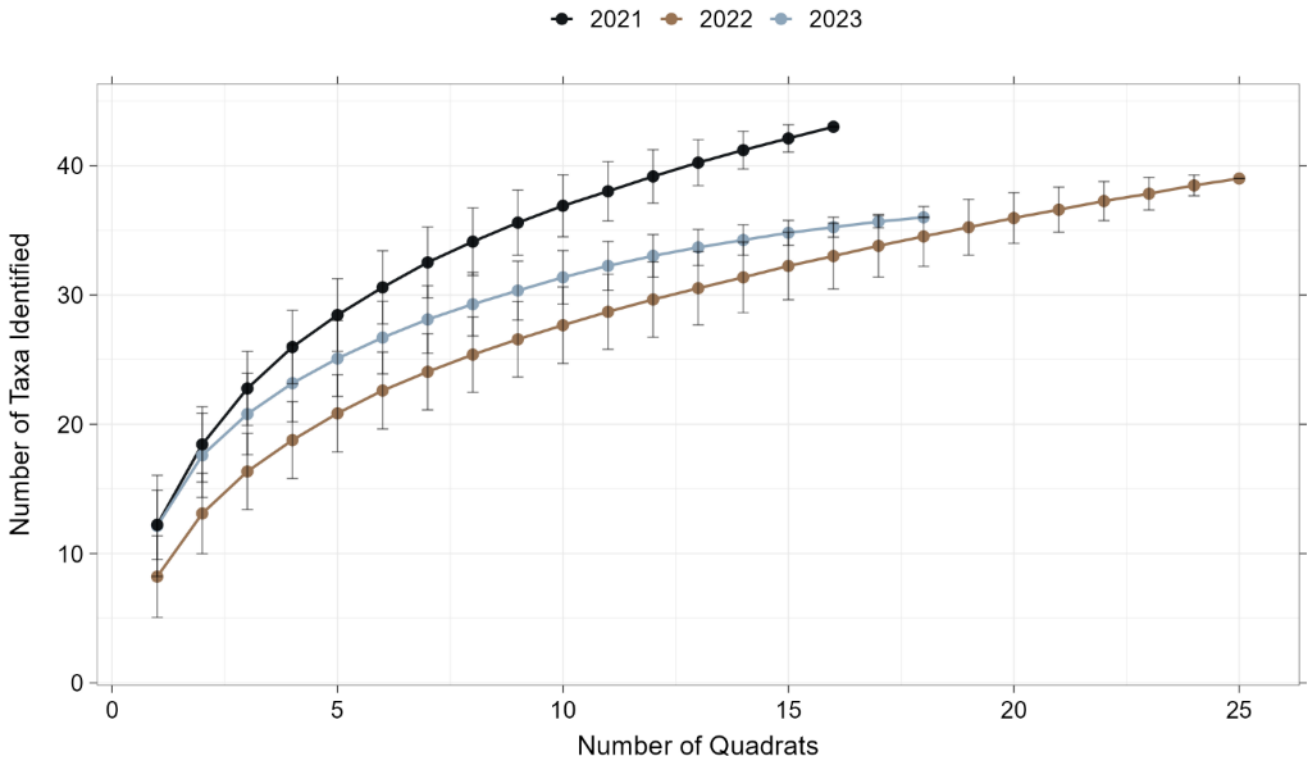
Dashed lines represent the mean percent cover for the exposure and reference quadrats for each year and stars represent years in which individual quadrats were not sampled.

Figure 5-15: A) Taxa Richness and B) Simpson's Diversity Index of Motile Epifauna Recorded in Quadrats Surveyed During Quadrat Surveys in Milne Port, 2021 – 2023.

5.4.4 2023 Relative Diversity

Taxa richness varied among quadrats for all major assemblages (macroflora, sessile epifauna, and motile epifauna) (Figure 5-16A). Generally, mean macroalgae and sessile epifauna taxa richness was similar within and across areas and higher than mean motile taxa richness, which was less than 3 taxa in both areas (Figure 5-12A). Statistical analysis indicated differences in taxa richness for macroflora and sessile epifauna between years but not between areas (Table 5-3). Overall, Q7 in the reference area supports the greatest taxa richness for macroalgae and sessile epifauna while seven quadrats (Q1, Q4, Q5, Q7, Q13, Q15, and Q20) had similarly high taxa richness for motile epifauna (Figure 5-16A). Q12 in the exposure area supports the lowest macroalgae and sessile epifauna taxa richness, consistent with 2022, while Q9, Q10, and Q23 supported the lowest epifauna taxa richness (Figure 5-16A).

SDI for macroflora ranged from low to high while sessile and motile epifauna ranged from very low to high (Figure 5-16B); statistically significant differences in SDI were found for macroflora between years but not among sampling areas (Table 5-3). Overall, Q5, Q8, Q13 (in the exposure area) and Q18 (in the reference area) displayed the greatest universal diversity, where macrofauna, sessile and motile epifauna SDI values were characterized as moderate to high (Figure 5-16B). Q12 and Q23 were the only quadrats to have very to moderate diversity values for the three types of assemblages and Q12 stands out as having the only very low diversity value for macroflora (Figure 5-16B).



Dashed lines represent the mean percent cover for the exposure and reference quadrats for each year.

Figure 5-16: A) Taxa Richness and B) Simpson's Diversity Index (SDI) for Macroalgae, Sessile Epifauna, and Motile Epifauna in Milne Port (2023)

5.4.5 Species Accumulation Curve and Sampling Effort

A taxa accumulation curve was calculated for quadrats surveyed in 2021 to 2023 to provide an estimate of the effort required to fully characterize the quadrat benthic community assemblage (macroalgae, sessile and motile epifauna) (Figure 5-17). While reaching an asymptote within a subsample of a locality is rare, this would indicate that nearly all species have been detected within the location sampled given the level of sampling effort. For years 2021 to 2023, the three curves approached, but did not reach, an asymptote for the number of quadrats sampled in each year. This indicates that sampling in all three years did not reach levels to fully describe the overall benthic community assemblage.

Mean number of taxa identified (solid circles) and one standard deviation (error bars) are shown for each sampling year. Values were determined using 999 permutations.

Figure 5-17: Mean Taxa Accumulation Curve for Quadrat Benthic Community Assemblage in Milne Port, 2021 – 2023.

5.4.6 Opportunistic Observations

Saddled Eelpouts (Appendix 5B – Photo 20 and 21) were observed residing within the hollow frame of six quadrats: Q12, Q14, and Q15 (exposure area) and Q7, Q17, and Q19 (reference area). Eelpouts were also observed within quadrats Q7 and Q15 in 2022 (Appendix 5C). This is the third year that eelpouts have been observed within the quadrat frames (Q1 in 2021), with identification of the eelpout to species level possible due to one eelpout that came out of the frame during the survey. A Shorthorn Sculpin (*Myoxocephalus scorpius*) was observed on top of the settlement substrate (Chapter 8.0) buoy (Appendix 5B – Photo 22) and an Arctic Sculpin was observed outside of the quadrat at Q9 in the reference area (Appendix 5B – Photo 23). Numerous Fish Doctors were observed coming out of the settlement baskets near the quadrat frames during retrieval (Appendix 5B – Photo 24).

Additionally, nudibranchs and eggs were observed on the chains anchoring the settlement plates, as well as the plates themselves, above the quadrats at Q7, Q8, Q9, Q10, and Q18 (Appendix 5B – Photo 25). A large unidentified nudibranch (Order Nudibranchia) was also observed outside of the quadrat at Q9 (Appendix 5B – Photo 26). Barnacles (Order Balanomorpha) and unidentified tunicates (Subphylum Tunicata) were also observed on the settlement substrates suspended above the quadrat at Q7, Q10 (Appendix 5B – Photo 27).

Brittle stars, blunt gaper clams, and a common sunstar (*Crossaster papposus*) (Appendix 5B – Photo 28) were observed in the area surrounding Q12 in the exposure area. Mysid shrimp (Order Mysida) were observed in abundance in the water column at quadrats Q1 and Q13 in the exposure area and Q7 in the reference area and a sea angel was observed above Q17 in the reference area (Appendix 5B – Photo 29).

There were no observations of deceased bivalves, some with blackened siphon ends, as observed within and outside of survey quadrats in both areas in 2022 (WSP 2023).

5.5 Discussion

Substrate type was similar among quadrats and between the exposure and reference areas. Substrate within the quadrats was dominated by soft substrate (silt and sand), consistent with what has been previously documented (Golder 2022; WSP 2023). Statistically significant interannual differences in soft substrate percent cover were attributed to interannual variations in gravel as well as the 2022-deployed quadrats (Q21-Q26), which generally contained higher percentages of coarse substrate in 2022.

Similar macroflora and benthic epifaunal taxa were observed in 2023 as in previous years (2018 to 2022) and indicators (i.e., percent cover, density, and diversity) were variable among quadrats. Variability is expected for this component of the MEEMP, given the dynamic coastal environment of Milne Inlet: factors such as freshwater input, sediment transport processes, and ice scour influence the percent cover/density and distribution of species in any given year. Indicators were not significantly different between exposure and reference area in 2023; however, interannual differences were observed in macroalgae and sessile taxa richness, as well as macroalgae SDI, with increases observed in these indices in 2023 compared to 2022. Additionally, macroalgae percent cover increased significantly within the reference area in 2023 compared to the previous two years. Motile epifauna density decreased compared to previous years in both areas; however, this decrease was driven by motile densities in Q6, which saw very high (outlier) motile densities in 2021 and 2022 but was not surveyed in 2023. When Q6 was excluded from models, reference area motile density increased in 2023 from 2022 densities. There was, in addition, some shift in taxa composition within the broader categories of organism types that may be attributable

to interannual variability. For example, brittle stars and green urchins that were observed at high densities in 2022 and 2021 were rarely observed in 2023; cooler temperatures and shorter open-water period associated with the late ice cover may have resulted in suboptimal conditions for green urchins (Blicher et al. 2007; Filbee-Dexter et al. 2022).

Overall, there was no evidence of project-related effects on substrate, macroflora, or benthic epifauna, demonstrated by similar temporal variation observed among both sampling areas, suggesting regional-level drivers of interannual variation.

5.6 Conclusions and Recommendations

Overall, macrofloral and benthic epifaunal community assemblages were comparable between exposure and reference areas though some indicators varied interannually, likely driven by natural environmental factors (e.g., temperature, salinity, ice scour, ice cover). Monitoring efforts to date revealed no evidence of overarching spatial or temporal trends that might be associated with Project-induced effects from construction or operation activities and Milne Port. Monitoring of macroflora and benthic epifauna assemblages should continue using the same sampling and statistical design.

In 2024, Q16 should be relocated, and a new time series started for that quadrat under a new name (e.g., Q27). Additionally, it is recommended to continue to monitor for opportunistic observations of deceased bivalves (as seen in 2022) and unknown taxa and that samples should be collected, when possible, for analyses and identification.

The power analyses found sufficient power to detect larger changes in substrate, epifauna and macroflora. Given the low statistical power to detect effect sizes that may be of biological relevance, going forward, it is recommended that conclusions are not made based on strict adherence to statistical significance. Instead, effect size, uncertainty, and statistical significance and power should be considered together before ruling out spatial and temporal changes in benthic infauna.

5.7 Closure

We trust this information is sufficient for your needs at this time. Should you have any questions or concerns, please do not hesitate to contact contact Phil Rouget, on behalf of the undersigned, at +1 250 419 4945.

APPENDIX 5A

DFO's Marine Foreshore Environmental Assessment Procedures

MARINE FORESHORE ENVIRONMENTAL ASSESSMENT PROCEDURE

Marine development projects have the potential to effect fish[1] and fish habitat[2]. Fisheries and Oceans Canada (DFO) is responsible for the protection and management of fish habitats under the authority of the *Fisheries Act* and may request plans, specifications and environmental assessments specific to marine projects where more detailed information is required. Assessments may be necessary for all types of projects, including, but not limited to aquaculture, log handling, industrial port development, marinas, private moorage facilities, marine repair facilities, pipeline or outfall installations, vessel launches or barge ramps, dredging projects and shoreline protection projects (breakwaters and seawalls). Presented below are standardized, transect-based assessment procedures intended to provide DFO with the basic information required to determine the potential effects of a development project on fish habitat.

Assessment Area

For comparative purposes, the assessment area should include both the foreshore site proposed for development as well as the adjacent foreshore. This will provide a context for the project and may provide data about cumulative effects if similar developments already occur on-site. A large scale site plan, preferably an enlargement of the hydrographic chart, with a small scale insert of the general geographic location will serve as a base map of the study area.

Tidal Height and Water Depth Measurements

The lowest normal tide (0.0 m), or chart datum, will be used as the reference point for the measurement of tidal height and water depth. Tidal height is recorded as positive relative to chart datum, while water depth below chart datum will be recorded as a negative value. For example, if the assessment is made when the tide is at 2 m, and observations are taken at a water depth of 6 m, then the depth will be recorded as -4 m. Tidal height will be corrected using the closest secondary port to the reference port found in the Canadian Tide and Current Tables, with further correction made for daylight savings time as required.

Transect Layout

Transects should be established perpendicular to the shoreline at regular intervals both within and adjacent to the proposed or active development area so as to sample representative fish habitat conditions. A preliminary low water reconnaissance or dive survey may be advisable to establish

---

[1] shellfish, crustaceans, marine animals and any parts of shellfish, crustaceans or marine animals, and the eggs, sperm, spawn, larvae, spat and juvenile stages of fish, shellfish, crustaceans and marine animals;

[2] shellfish, crustaceans, marine animals and any parts of shellfish, crustaceans or marine animals, and the eggs, sperm, spawn, larvae, spat and juvenile stages of fish, shellfish, crustaceans and marine animals;

appropriate boundaries for the assessment. Transects should begin at the highest high water mark (HHWM: distance referenced as Station 0.0 m) and, at a minimum, extend to a depth of -20 m (–30 m if the development has the potential to effect deeper benthic habitats). Though small-scale intertidal projects may only require intertidal transects, care must be taken to ensure that a representative sample is collected across the proposed development area. Procedural manuals are available from DFO if sampling of intertidal clam or benthic invertebrates is required. To ensure complete assessment of marine plants and animals in the photic zone, deeper transects may be necessary, especially to determine the effects of sunken debris or woodwaste accumulations resulting from existing developments. Transects should be spaced approximately 25 m apart, although this interval may vary depending on the width of the site. The number of transects required will depend on the nature of the foreshore development proposed, anticipated effects of the development, and local site conditions (tides and currents, geography, fetch, geology, etc.). Transects should be individually numbered and indicated on the site plan, and their commencement point referenced to benchmarks, where possible.

Recording Observations

Habitat inventories should be conducted during the more productive spring and summer months. At that time, algae and saltmarsh species are more readily identifiable, enabling a better assessment of the productive capacity of the site.

Observations should be recorded every 5 m along the transect or at significant changes in habitat type. Observations should include substrate type and composition, presence and relative abundance of marine animals and plants, and any other notable features (e.g., debris accumulations) using the following format:

Substrate

Substrate types are to be subdivided into the following size class categories:

- Bedrock
- Boulder (>256 mm diameter)
- Cobble (64-256 mm diameter)
- Gravel (2-64 mm diameter)
- Sand (0.0625-2 mm diameter)
- Silt/Mud/Clay (<0.0625 mm diameter)

Substrate types are recorded cumulatively as percentages out of a total of 100% (e.g., Boulder 5%; Cobble 15%; Gravel 60%, Sand 20%)

Marine Plants

Marine plants include rooted vascular vegetation (e.g., eelgrass, saltmarsh vegetation, etc.) and marine algae (e.g., rockweed, kelp, etc.). Marine plant observations are recorded as percent areal coverage estimated per 5 m × 1 m transect segment. Observations can be recorded as percentages (5%, 10%, 15%, etc.) or by utilizing the following areal coverage classes:

+	<5%
1	5-25%
2	>25-50%
3	>50-75%
4	>75-100%

Sessile Animals

Many marine animals permanently attached to substrates function as important fish habitat (e.g., barnacles, bay mussels, etc.). Sessile animals are recorded as percent areal coverage along the transect line using either estimated percentages or by areal coverage classes, as presented above.

Motile Animals

Motile animals include fish and marine invertebrates such as crabs and snails. These can be individually counted along the transect or, where too numerous, their estimated numbers can be recorded. Population estimates will most likely be applied to species such as herring or mysid shrimp that naturally occur in large numbers.

Other Features

Accumulations of wood bark and debris, sunken logs or other waste materials arising from onsite or nearby development activities should also be recorded. For wood bark and related small size debris, observations are recorded as percent areal coverage estimates per 5 m × 1 m transect segment and estimated deposition depth (e.g., 15% / 10 cm). For larger materials (sunken logs, wood chunks, etc.), observations can be recorded by individual piece count or by estimate of percent areal coverage.

Observations should be correlated to the transect distance from the HHWM and (corrected) tidal height or water depth (e.g., Sta. 0+80 m / +4.5 m), with information compiled in tabular form, by transect. Common names of observed animals and plants are acceptable for the data table; a species list with scientific names should, however, be appended to the report.

General marine plant categories (e.g., rockweed, eelgrass, bull kelp, saltmarsh, etc.) and any other notable features should be sketched to scale directly on a copy of the site plan, drawings or photographs of the site. A site profile should be prepared for each transect showing the slope of the foreshore and the location of indicator marine plants or invertebrates. A sketch of the proposed marine development should be superimposed over the site plan so that any potential effect of the project on fish habitat is clear. Compensatory habitat proposed for offsetting altered habitat should also be sketched on site maps and profiles to enable review of the positioning of replacement habitat relative to the project.

Photographic Documentation

It is essential to produce a photographic record along the intertidal and subtidal transects. A videographic record of subtidal transects is also recommended. Photos and videos provide a real-time record of characteristic fish habitat at the proposed site and can be invaluable to future post-development site monitoring. Photographic records also facilitate comparison of the productivity of natural habitats with any compensatory habitat constructed to offset habitat losses. As visibility may be a problem, careful attention should be given to appropriate tidal levels, and midday lighting conditions are recommended. Aerial photos, taken at low tide, are often useful to put the site into context with the surrounding area and to verify information provided from other sources.

Assessment reports should include photographs of representative fish habitat types. Depending upon the scope of the proposed foreshore development, an unedited, labelled copy of the assessment video may also be required for the report submission. The video footage should be referenced with pertinent information (e.g., time, date, depth, heading, etc.), and a written or recorded interpretation should accompany the video.

Summary of information to be submitted

1. Basemap showing tenure area boundaries, surrounding area, transect locations and sampling stations
2. Shoreline video/photographs of intertidal zone
3. Underwater video/photographs of transects
4. Tabular data for each transect describing substrate type and composition, marine plants, sessile and motile marine animals, and other notable features
5. Habitat map showing location of different substrate types, plants, animals and operational infrastructure
6. Profile diagrams of each transect showing slope, sediment types and the major marine plants or animals observed
7. Photographs of site and aerial photographs if available.

APPENDIX 5B

Photographs

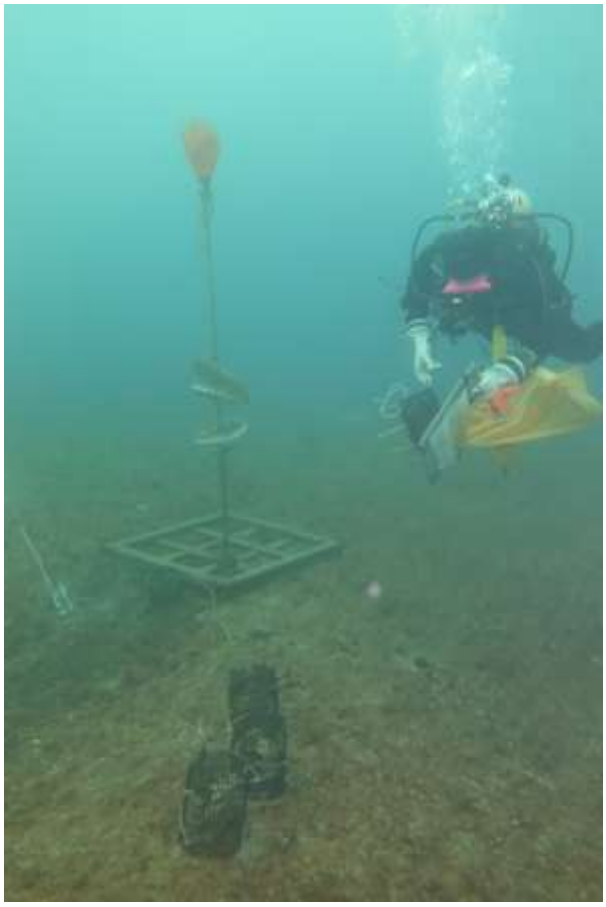

Photo 1: WSP diver surveying Q4 within the exposure area (25 July 2023).

Photo 2: Sugar kelp (*Saccharina latissima*) in Q4 within the exposure area (25 July 2023).

Photo 3: Rockweed (*Fucus distichus*) and green filamentous algae *Chaetomorpha melagonium* in Q8 within the reference area (29 July 2023).

Photo 4: Brown filamentous algae *Pylaiella sp.* (blue arrow), rockweed (*Fucus distichus*; red arrow), green filamentous algae *Chaetomorpha melagonium* (yellow arrow), acid weed (*Desmarestia sp.*; purple arrow), and small sabellid worm sp. 1 (Family Sabellidae) in Q13 within the exposure area (31 July 2023).

Photo 5: Brown filamentous algae *Pylaiella sp.* in Q23 within the exposure area (27 July 2023).

Photo 6: Acid weed (*Desmarestia sp.*) and red foliose algae *Coccotylus truncatus* in Q4 within the exposure area (25 July 2023).

Photo 7: Red filamentous algae *Savoiea arctica* on an Icelandic scallop (*Clamys islandica*) in Q3 within the exposure area (31 July 2023).

Photo 8: Unidentified red branched algae (Phylum Rhodophyta; blue arrow) and a Saddled eelpout *(Lycodes mucosus*) in Q7 within the reference area (29 July 2023).

Photo 9: Nudibranch (*Dendronotus sp.*) collected for laboratory taxonomic identification and wrinkled rock borer clams (*Hiatella arctica*) in Q9 within the reference area (29 July 2023).

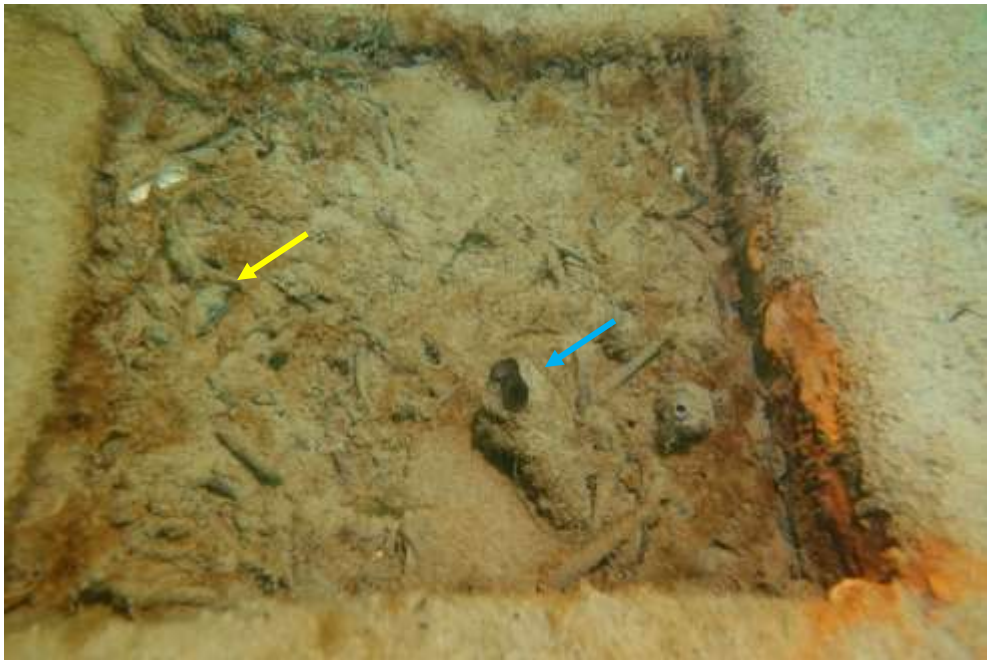

Photo 10: Blunt gaper clam (*Mya truncata*; blue arrow) and a discord mussel (*Musculus discors*; yellow arrow) in Q9 within the reference area (29 July 2023).

Photo 11: Whelk (Family Buccinidae) and cone worm (*Cistenides granulata*) in Q15 within the exposure area (26 July 2023).

Photo 12: Small sabellid worm sp. 1 (Family Sabellidae; blue arrow), large sabellid worm sp. 2 (Family Sabellidae; yellow arrow), and green filamentous algae *Chaetomorpha melagoniumin* in Q4 within the exposure area (25 July 2023).

Photo 13: Shrimp (Superfamily Pandaloidea) in Q20 within the reference area (31 July 2023).

Photo 14: Crangon shrimp (Family Crangonidae) in Q8 within the reference area (29 July 2023).

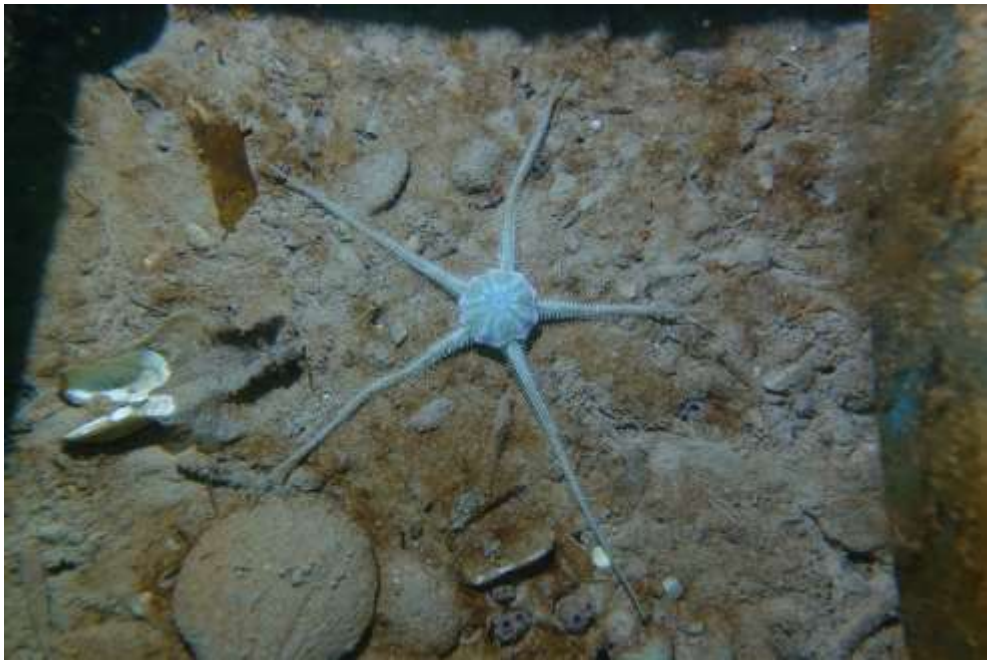

Photo 15: Brittle star (Family Ophiuroidea) in Q3 within the exposure area (31 July 2023).

Photo 16: Green urchin (*Strongylocentrotus droebachiensis*) in Q12 within the exposure area (2 August 2023).

Photo 17: Six-rayed sea star (*Leptasterias sp.*) in Q4 within the exposure area (25 July 2023).

Photo 18: Burrowing anemone (Subclass Ceriantharia; blue arrow) in Q7 within the reference area (29 July 2023).

Photo 19: Juvenile Lumpfish (*Cyclopterus lumpus*) in Q8 within the reference area (29 July 2023).

Photo 20: Opportunistically observed Saddled Eelpout (*Lycodes mucosus*) inside the frame of Q14 within the exposure area (25 July 2023).

Photo 21: Opportunistically observed Saddled Eelpout (*Lycodes mucosus*) coming out of the frame of Q17 within the reference area (29 July 2023).

Photo 22: Opportunistically observed Shorthorn Sculpin (*Myoxocephalus scorpius*) on the settlement substrate buoy above Q9 within the reference area (29 July 2023).

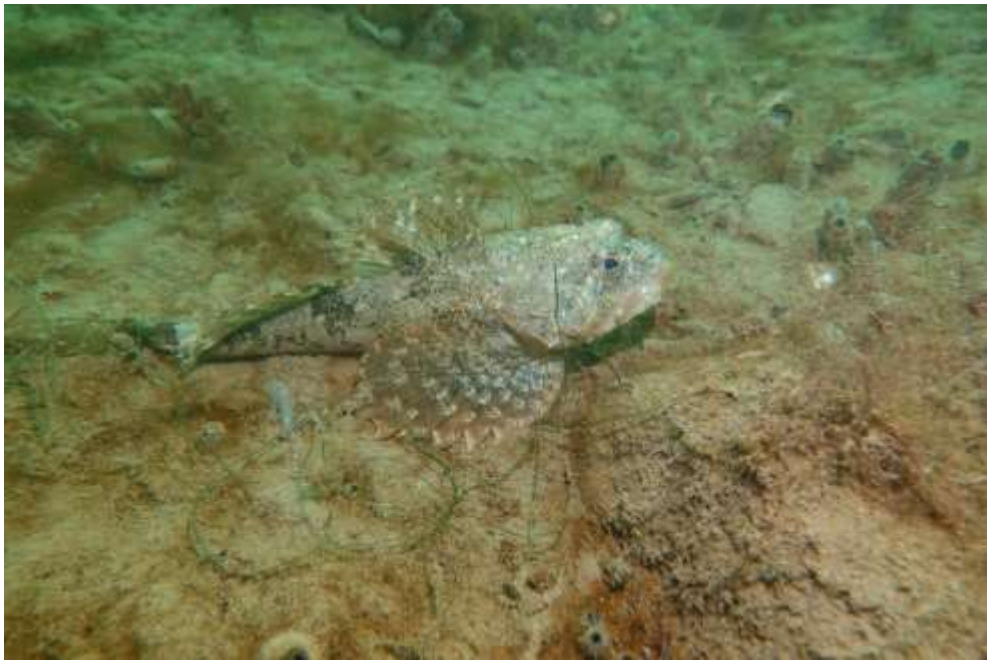

Photo 23: Opportunistically observed Arctic Sculpin (*Myoxocephalus scorpioides*) outside Q9 within the reference area (29 July 2023).

Photo 24: Opportunistically observed Fish Doctor (*Gymnelus viridis*), often observed coming out of settlement baskets, outside Q9 within the reference area (29 July 2023).

Photo 25: Opportunistically observed nudibranch eggs (Order Nudibranchia, potentially from *Dendrotus sp.*) above Q9 within the reference area (29 July 2023).

Photo 26: Opportunistically observed nudibranch (Order Nudibranchia) outside Q9 within the reference area (29 July 2023).

Photo 27: Opportunistically observed tunicates (Subphylum Tunicata) outside of Q7 within the reference area (29 July 2023).

Photo 28: Opportunistically observed common sunstar (*Crossaster papposus*) outside of Q12 within the exposure area (2 August 2023).

Photo 29: Opportunistically observed sea angel (*Clione limacina*) above Q17 within the reference area (29 July 2023).

APPENDIX 5D

2023 Taxa List

Taxa Identified During 2023 Quadrat Surveys in Milne Port, NU

Macroflora	
Common Name	**Scientific Name**
Sieve kelp	*Agarum clathratum*
Sugar kelp	*Saccharina latissima*
Acid weed	*Desmarestia sp.*
Rockweed	*Fucus distichus*
Brown filamentous	*Pylaiella sp.*
Green filamentous	*Chaetomorpha melagonium*
Green filamentous	Chlorophyta indet.
Red foliose	*Coccotylus truncatus*
Red filamentous	*Savoiea arctica*
Red filamentous	Rhodophyta indet.
Red branched	
Encrusting coralline	Corallinales indet.

Sessile Epifauna	
Common Name	**Scientific Name**
Barnacle	**Balanomorpha indet.**
Cone worm	*Cistenides granulata*
Small sabellid worm sp. 1	Sabellidae indet.
Large sabellid worm sp. 2	Sabellidae indet.
Burrowing anenome	Ceriantharia indet.
Astarte clam	*Astarte sp.*
Icelandic scallop	*Chlamys islandica*
Wrinkled rock-borer	*Hiatella arctica*
Discord mussel	*Musculus discors*
Blunt gaper	*Mya truncata*
Clam	*Mya sp.*
Mussel	Mytilida indet.
Orange tunicate	*Polycarpa sp.*
Tunicate	**Tunicata indet.**

Motile Epifauna	
Common Name	**Scientific Name**
Amphipod	Amphipoda indet.
Shrimp	Crangonidae indet.
Mysid shrimp	Mysida indet.
Shrimp	Pandaloidea Indet.
Six-rayed sea star	*Leptasterias sp.*
Brittle star	Ophiuroidea indet.
Green urchin	*Strongylocentrotus droebachiensis*
Whelk	Buccinidae indet.
Sea angel	***Clione limacina***
Common sunstar	***Crossaster papposus***
Nudibranch	*Dendronotus sp.*
Black snail	Gastropoda indet.
Limpet	Patellogastropoda indet.
Margarite snail	*Margarites spp.*
Nudibranch	Nudibranchia Indet.

Fishes	
Common Name	**Taxa Name**
Fish Doctor	***Gymnelus hemifasciatus***
Saddled Eelpout	*Lycodes mucosus*
Lumpfish	*Cyclopterus lumpus*
Shorthorn Sculpin	***Myoxocephalus scorpius***
Arctic Sculpin	*Myoxocephalus scorpioides*
Sculpin	Cottidae indet.

Note: taxa in **Bold** indicate opportunistic sighting taxa only, not taxa that was observed within the permanent quadrats.

APPENDIX 5E

Power Analysis

POWER ANALYSIS - METHODS

A Type I error is concluding there is a significant effect when none exists (i.e., a false positive). Alpha (α) is the probability of committing a Type I error. A Type II error is the probability of concluding there is no significant effect when there is a real effect of some specified magnitude (i.e., a false negative). Beta (β) is the probability of committing a Type II error. The power of a statistical test (1 - β) is the probability of detecting a real effect. In this analysis, the Type I error-rate (α), also referred to as the significance level, was set to 0.05. The desired minimum statistical power was 80%, which corresponds to a type II error-rate of 0.2. Power analyses were conducted to assess the power of statistical tests under multiple effect sizes. For each model, a set of effect sizes was created, so that power is assessed at a range of effect sizes. Both negative and positive effect sizes were used, to assess the power of detecting either a reduction or an increase in values of the response variables. Since the analysis focused on assessment of changes to statistical power at different effect sizes, the power analysis used the observed samples sizes from the collected data.

Data Simulation following Effect Size Application

The power to detect statistically significant effects was estimated using residual bootstrapping in R v. 4.3.2 (R 2023), following the approach of Fox and Weisberg (2018). The general approach was to simulate data based on the model selected for interpretation, the observed sample size, and the residuals, and re-run the models that were used for the original analysis using the simulated data. The data simulation and analysis were repeated 2,000 times, and the proportion of repetitions where the *P*-values of interest were significant ($P<0.05$) was interpreted as the statistical power of the test.

To produce simulated data, the original model was used to predict values of the response variable. The predicted values were then adjusted according to the effect size, depending on the analysis (see below for details). The simulated data were then analyzed using the same model structure as the original analysis. Effect sizes and statistical tests were applied differently to different models, as detailed below.

Effect Sizes

In this power analysis, the question of interest was the models' power to detect between-area differences at various effect sizes. To assess the power to detect differences between the reference and exposure areas, given the data collected prior to 2023, the effect size was applied to 2023 data collected at the exposure area only; that is, all other years and all reference area data had an effect size of zero. The effect sizes were calculated relative to the observed values at the reference area in 2023. An example of the effect size application for soft substrate content is provided in Figure 5E-1. The simulated data based on effect sizes applied to values of the response variable from 2023 reference area were combined with simulated data from previous years (with an effect size of zero). This combined dataset was analyzed using the models from the original analysis in the main report.

To estimate the power to detect a difference between reference and exposure areas in 2023, the significance of the interaction between year (as a categorical variable) and area was calculated for each simulation. The proportion of repetitions with *P*-values less than 0.05 was interpreted as the statistical power to detect an effect.

Power Analysis – Reporting of Results

Power curves were produced, showing statistical power as a function of effect size in percentages. Horizontal lines were added to visualize statistical power values of 0.8 (hereafter sufficient power) and 0.9 (hereafter high power), and a vertical line was added to visualize the magnitude of difference that was observed in the original analysis.

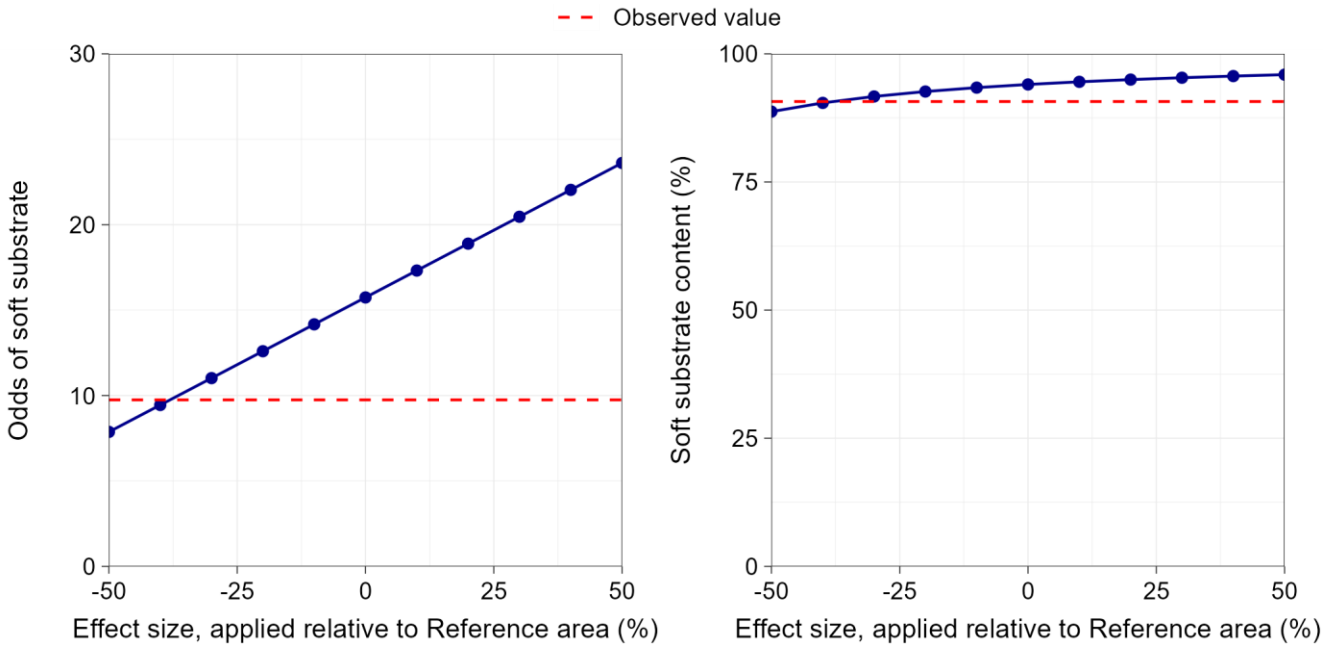

Figure 5E-1: Application of effect sizes to examine effect of area on soft substrate content, illustrating how effect sizes applied on the odds scale (left) are affected by the bounding of soft substrate content by 0% and 100% once effect sizes are expressed on the percent scale (right).

POWER ANALYSIS – RESULTS

Substrate

The analysis of soft substrate content had sufficient power (>0.8) to detect a significant year and area interaction at effect sizes of -50% and +162% Figure 5E-2). That is, when the 2023 exposure area had mean soft substrate content that was 50% lower or 162% higher (on the odds scale) than the 2023 reference area, the model could detect a significant interaction between year and area. The observed effect size in 2023 was -34%, and statistical power to detect the effect was low (<0.7). This is consistent with the lack of a significant interaction in the original analysis (Section 5.4.1 in the 2023 MEEMP main report [WSP 2024]). The model had higher power to detect decreases than increases in soft substrate, due to the high values of soft substrate observed in 2023 (Section 5.4.1 in the 2023 MEEMP main report [WSP 2024]) and the bounding of the variable by 0% and 100% (Figure 5E-2).

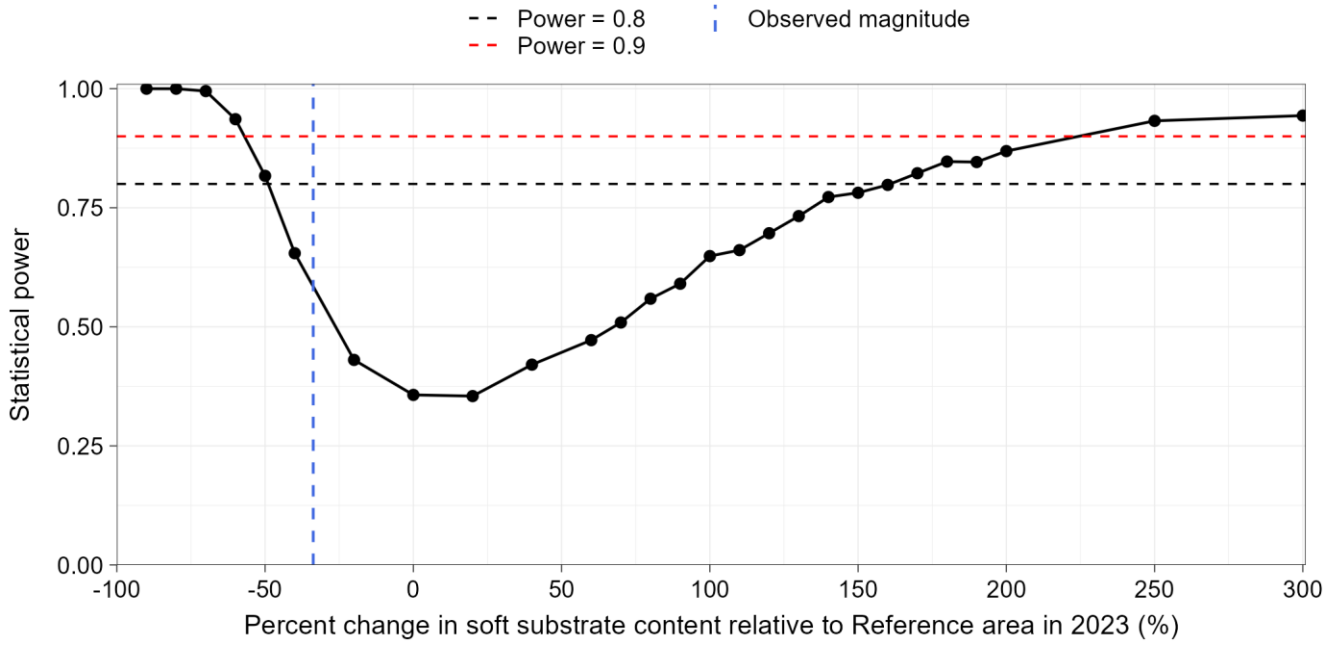

Figure 5E-2: Statistical power of the 2021-2023 soft substrate model to detect a significant interaction between year and area; observed effect size is shown as a vertical line.

Macroflora

The analysis of macroflora percent cover did not have sufficient power to detect a significant interaction at any of the examined effect sizes (Figure 5E-3). The observed effect size in 2023 was -69%, and statistical power to detect the effect was low (<0.3). This is consistent with the lack of a significant interaction in the original analysis (Section 5.4.2 in the 2023 MEEMP main report [WSP 2024]). Due to the high variability in percent cover of macroflora, the model had low power to detect both decreases and increases in values relative to the reference area.

The analysis of macroflora species richness had sufficient power (>0.8) to detect a significant year and area interaction at effect sizes of -62% and +102% (Figure 5E-3). That is, when the 2023 exposure area had mean macroflora richness 62% lower or 102% higher than the 2023 reference area, the model could detect a significant interaction between year and area. The observed effect size in 2023 was -13%, and given this small effect size, statistical power to detect it was low (<0.2). This is consistent with the lack of a significant interaction in the original analysis (Section 5.4.2 in the 2023 MEEMP main report [WSP 2024]).

The analysis of macroflora Simpson's Diversity Index had sufficient power (>0.8) to detect a significant year and area interaction at an effect size of +312%, but not at any of the negative effect sizes (Figure 5E-3). That is, when the mean macroflora SDI value in the 2023 exposure area was 312% higher than the 2023 reference area (on the odds scale), the model could detect a significant interaction between year and area. The observed effect size in 2023 was +43%, and statistical power to detect it was low (<0.3). This is consistent with the lack of a significant interaction in the original analysis (Section 5.4.2 in the 2023 MEEMP main report [WSP 2024]).

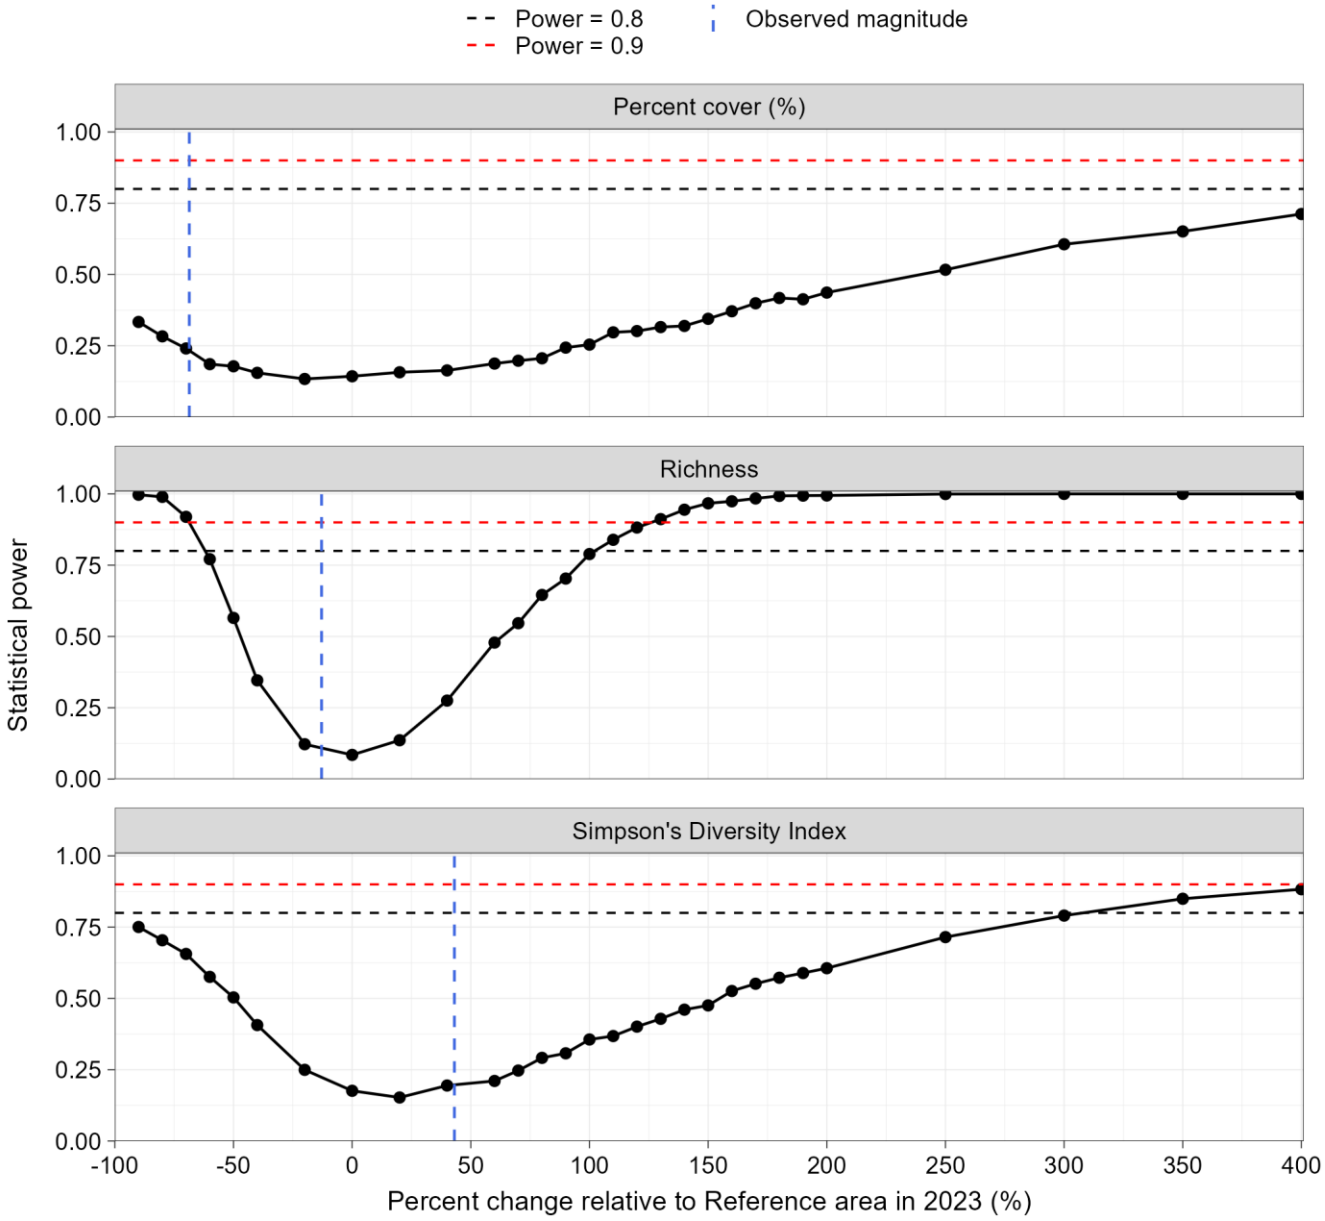

Figure 5E-3: Statistical power of the 2021-2023 macroflora models to detect a significant interaction between year and area; observed effect size is shown as a vertical line for each of the three variables.

Sessile Epifauna

The analysis of sessile epifauna percent cover did not have sufficient power to detect a significant interaction at any of the examined effect sizes (Figure 5E-4). The observed effect size in 2023 was -27%, and statistical power to detect the effect was low (<0.3). This is consistent with the lack of a significant interaction in the original analysis (Section 5.4.3.1 in the 2023 MEEMP main report [WSP 2024]). Due to the high variability in percent cover of sessile epifauna, the model had low power to detect both decreases and increases in values relative to the reference area.

The analysis of sessile epifauna richness had sufficient power to detect a significant interaction at effect sizes of -72% and +71% (Figure 5E-4). That is, when the 2023 exposure area had mean sessile epifauna richness 72% lower or 71% higher than the 2023 reference area, the model could detect a significant interaction between year and area. The observed effect size in 2023 was -12%, and statistical power to detect the effect was low (<0.3). This is consistent with the lack of a significant interaction in the original analysis (Section 5.4.3.1 in the 2023 MEEMP main report [WSP 2024]).

The analysis of sessile epifauna Simpson's Diversity Index had sufficient power to detect a significant interaction at an effect size of +213%, but not at any of the examined negative effect sizes (Figure 5E-4). That is, when the 2023 exposure area had mean sessile epifauna SDI that was 213% higher than the 2023 reference area (on the odds scale), the model could detect a significant interaction between year and area. The observed effect size in 2023 was -40%, and statistical power to detect the effect was low (<0.3). This is consistent with the lack of a significant interaction in the original analysis (Section 5.4.3.1 in the 2023 MEEMP main report [WSP 2024]).

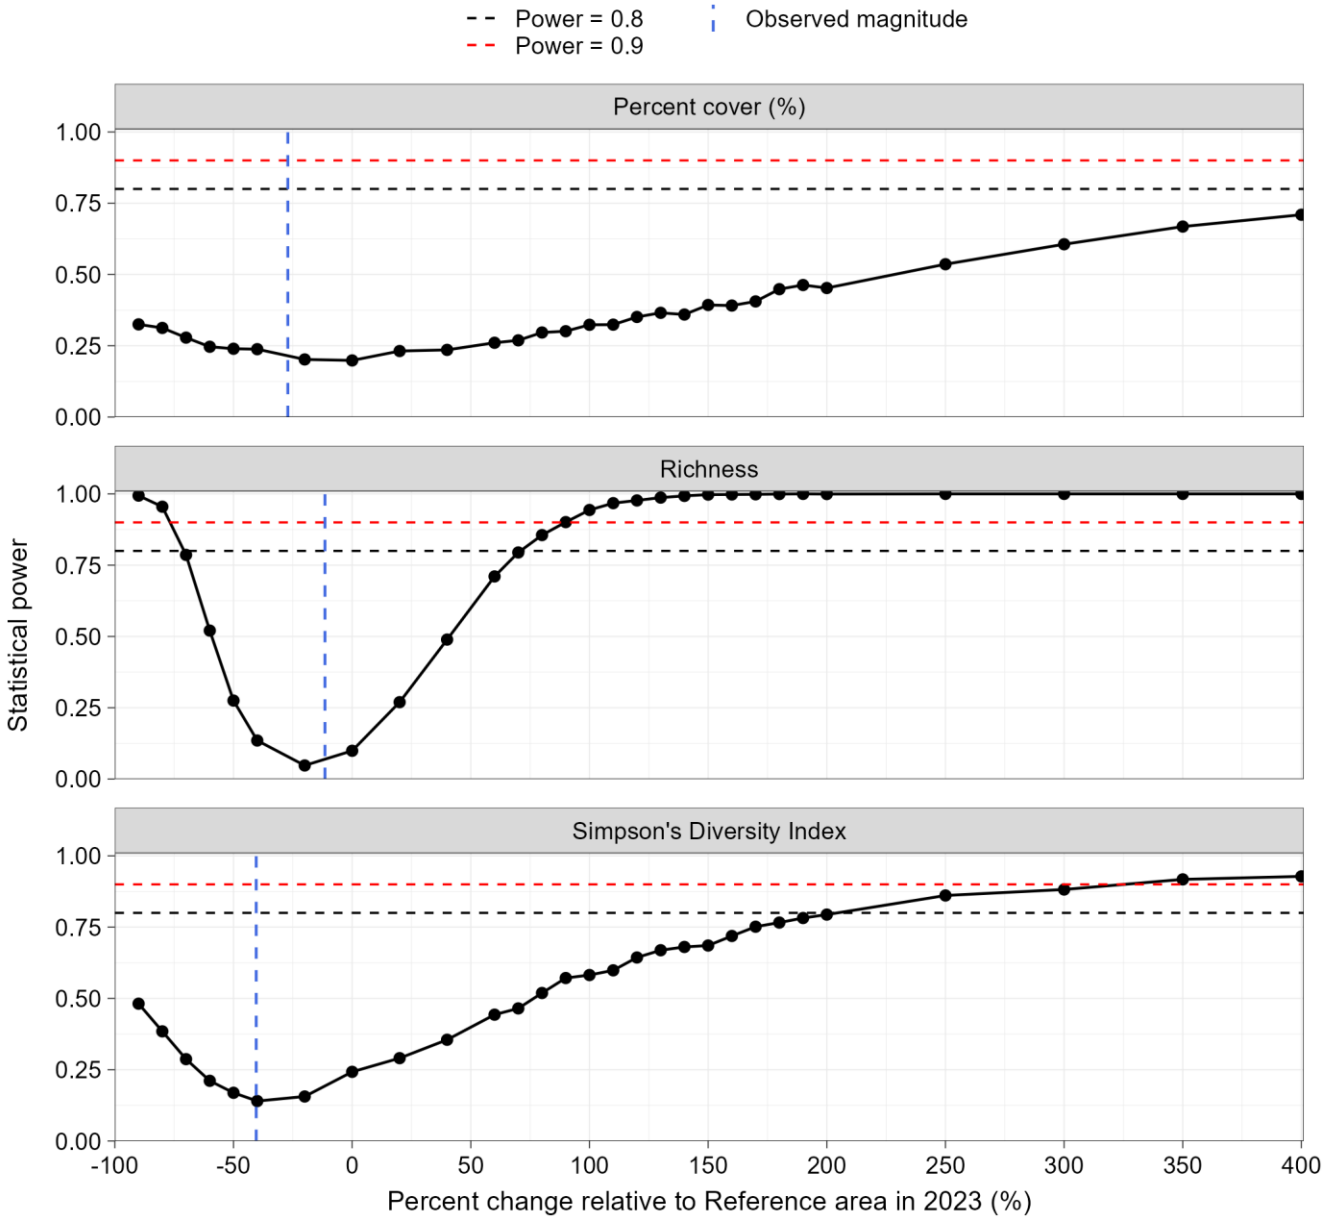

Figure 5E-4: Statistical power of the 2021-2023 sessile epifauna models to detect a significant interaction between year and area; observed effect size is shown as a vertical line for each of the three variables.

Motile Epifauna

The analysis of motile epifauna density had sufficient power to detect a significant interaction at effect sizes <+30% and >+172% (Figure 5E-5). That is, when the 2023 exposure area had mean motile epifauna density that was less than 30% higher or more than 172% higher than the 2023 reference area, the model could detect a significant interaction between year and area. The observed effect size in 2023 was -16%, and statistical power to detect the effect was high (>0.9). This is consistent with finding a significant interaction in the original analysis (Section 5.4.3.2 in the 2023 MEEMP main report [WSP 2024]). The power to detect an interaction was >0.7 for all examined effect sizes, due to the large difference between reference and exposure in 2022, but not in 2021, which resulted in a high proportion of simulations with a significant interaction between year and area. The estimated statistical power was at its lowest at effect sizes of approximately 60%–120% (Figure 5E-5), since at those effect sizes, the difference between reference and exposure areas in 2023 became similar to the difference between reference and exposure areas in 2022, and the statistical significance of the interaction decreased; instead, the main effect of area was significant more often.

The analysis of motile epifauna richness had sufficient power to detect a significant interaction at an effect size of +220%, but not any of the examined negative effect sizes (Figure 5E-5). That is, when the 2023 exposure area had mean motile epifauna richness that was 220% higher than the 2023 reference area, the model could detect a significant interaction between year and area. The observed effect size in 2023 was +32%, and statistical power to detect the effect was low (<0.3). This is consistent with the lack of a significant interaction in the original analysis (Section 5.4.3.2 in the 2023 MEEMP main report [WSP 2024]). The low power to detect decreases in richness was likely due to the variability associated with the observed data.

The analysis of motile epifauna Simpson's Diversity Index had sufficient power to detect a significant interaction at effect sizes of -88%, but not at any of the examined positive effect sizes (Figure 5E-5). That is, when the 2023 exposure area had mean motile epifauna SDI that was 88% lower (on the odds scale) than the 2023 reference area, the model could detect a significant interaction between year and area. The observed effect size in 2023 was +129%, and statistical power to detect the effect was low (<0.5). This is consistent with the lack of a significant interaction in the original analysis (Section 5.4.3.2 in the 2023 MEEMP main report [WSP 2024]). The low power to detect increases in motile epifauna SDI was likely due to the variability associated with the observed data, as well as with the relatively low value of SDI in the reference area in 2023.

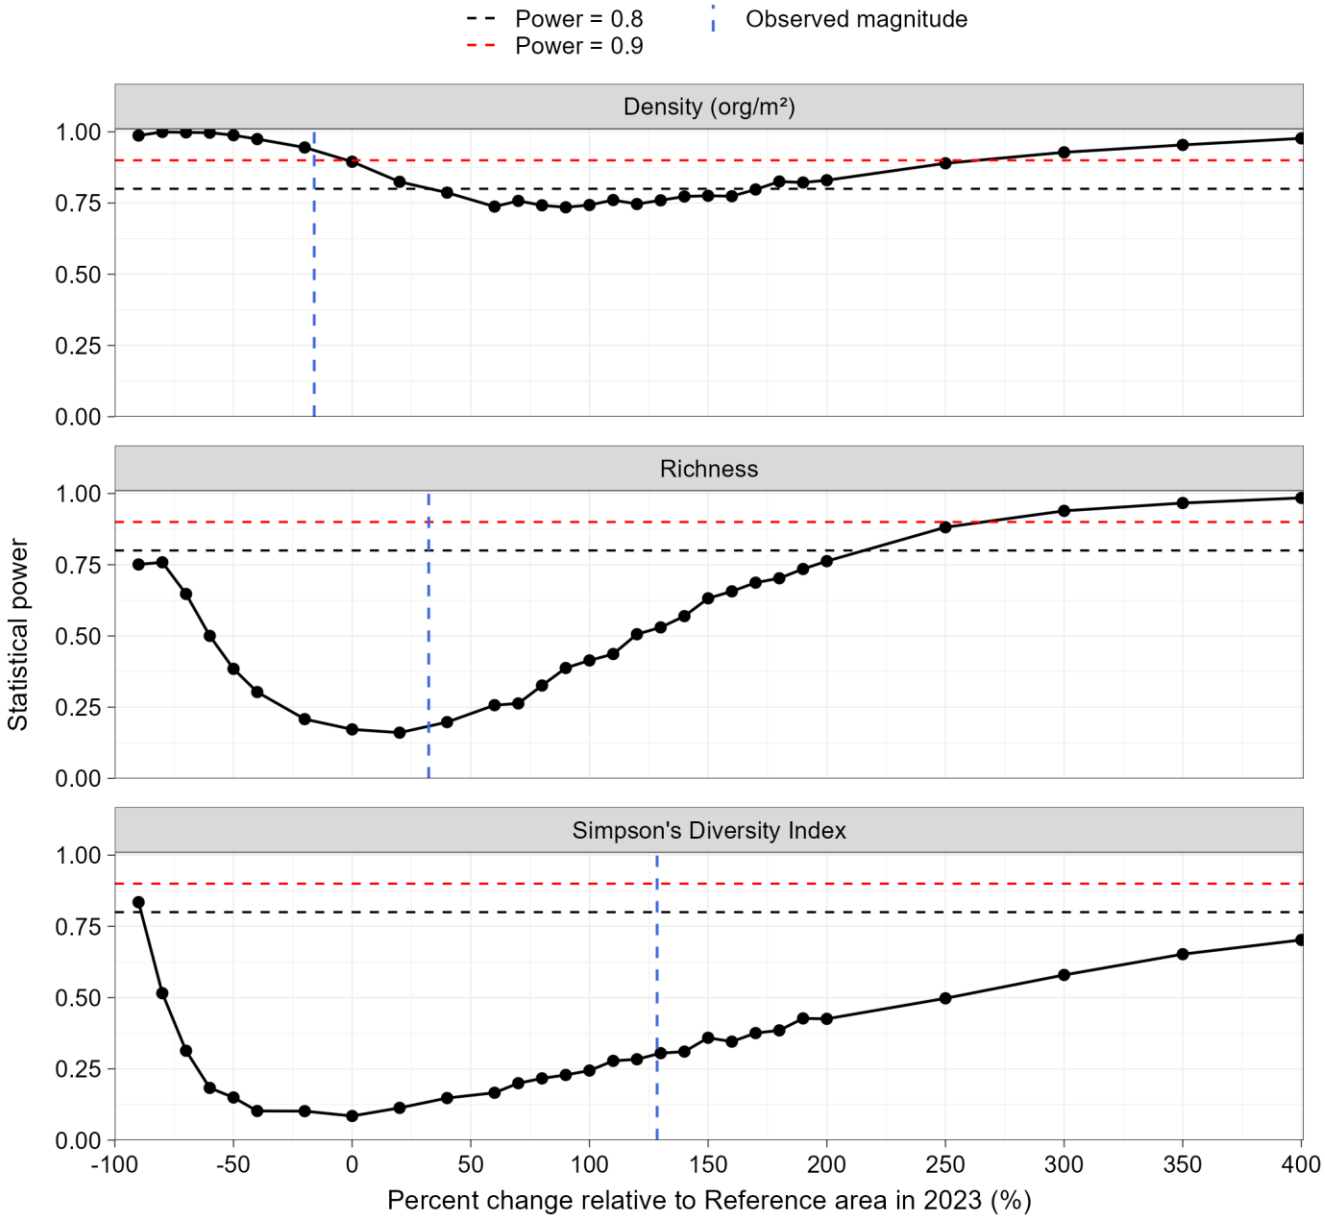

Figure 5E-5: Statistical power of the 2021-2023 motile epifauna models to detect a significant interaction between year and area; observed effect size is shown as a vertical line for each of the three variables.

POWER ANALYSIS – SUMMARY

Summary of Findings

- Substrate
  - Sufficient power to detect a significant year and area interaction in the analysis of soft substrate content at effect sizes of -50% and +162%.
- Macroflora
  - Percent cover: no sufficient power to detect a significant interaction at any of the examined effect sizes
  - Richness: sufficient power (>0.8) to detect a significant year and area interaction at effect sizes of -62% and +102%
  - Simpson's Diversity Index: sufficient power (>0.8) to detect a significant year and area interaction at an effect size of +312%, but not at any of the negative effect sizes
- Sessile epifauna
  - Percent cover: no sufficient power to detect a significant interaction at any of the examined effect sizes
  - Richness: sufficient power to detect a significant interaction at effect sizes of -72% and +71%
  - Simpson's Diversity Index: sufficient power to detect a significant interaction at an effect size +213%, but not at any of the examined negative effect sizes
- Motile epifauna
  - Density: had sufficient power to detect a significant interaction at effect sizes <+30% and >+172
  - Richness: had sufficient power to detect a significant interaction at an effect size of +220%, but not any of the examined negative effect sizes
  - Simpson's Diversity Index: sufficient power to detect a significant interaction at effect sizes of -88%, but not at any of the examined positive effect sizes

Implications of Power Analysis Results

Given the low statistical power to detect effect sizes that may be of biological relevance, going forward, it is recommended that conclusions are not made based on strict adherence to statistical significance. Instead, effect size, uncertainty, and statistical significance and power should be considered together before ruling out spatial and temporal changes in epifauna and macroalgal communities.

6.0 MARINE FISH COMMUNITY PROGRAM

6.1 Introduction

This chapter presents the results of the marine fish community program, a component of the larger Marine Environmental Effects Monitoring Program (MEEMP) conducted in Milne Inlet during the 2023 open-water season. This chapter was developed in consideration of the potential Project-related effects on marine fish and fish habitat as identified in the 2012 Final Environmental Impact Statement (FEIS) and subsequent addenda, as well as monitoring requirements outlined in the Project Certificate (PC) Conditions described in Chapter 1.0, Table 1-2. PC Conditions related to the monitoring of marine fish habitat include PC Conditions No. 99(b)(ii), 99(c), 113, and 114. This chapter complements Chapter 7.0 (Fish Health and Tissue Chemistry), which focuses on the health of the marine fish community in Milne Port, including length-frequency distributions, length-weight relationships, visual assessment of internal and external abnormalities, and tissue chemistry.

6.2 Objectives

The objectives of the MEEMP are outlined in Section 1.3 of Chapter 1.0 (Program Overview). The objectives specific to the marine fish community program component are as follows:

- Characterize the marine fish community at Milne Port in terms of species presence, number of fish caught, and relative abundance.
- Provide species-specific and overall Catch Per Unit Effort (CPUE) for each fishing method for 2023 catch data to better understand the efficacy of fishing methods at Milne Port.
- Compare 2023 catch statistics (total abundance and species composition) to previous years using annual data plots from 2020 to 2023.
- Test for differences in overall CPUE between 2020 to 2023 while accounting for differences in the location and number of sampling locations to better understand trends at Milne Port.

6.3 Study Design

The current study design for fishing reflects feedback from the Marine Environment Working Group (MEWG), while maintaining consistency with the design used during previous monitoring years to facilitate comparisons of results over time. For the period of 2014 to 2017, the study design remained largely unaltered except for the addition of angling (jigging and trolling) and a trial of minnow traps in 2017; from 2014 to 2017, sampling was conducted over a two-week period in August. In 2018, sampling duration was extended to four weeks of the open-water season instead of two weeks to provide greater sampling effort to better understand the fish community. During this extended sampling period, beach seining (“seine net”) was added as a supplemental fishing method (Table 6-1).

In 2019, the sampling duration was extended to five weeks of the open water season to continue to understand and represent the fish community. Hoop net traps (also known as fyke nets) were trialled during the 2019 MEEMP fish sampling program and fully added to the program in 2020 to be trialled for a minimum of three years as a potential replacement method for Fukui traps (Table 6-1). This addition was made following input from the MEWG regarding low capture efficiency in Fukui traps (DFO, QIA; 2018 MEEMP/AIS report comments, M-23042019,

M-21062019). The three-year trial comparing catches of hoop nets and Fukui traps was completed in 2022. It was decided to continue the comparison in 2023 with greater attention to matching fishing effort to ensure that conclusions about the catches of the two techniques were not biased by uneven sample size and soak times.

In 2020, the MEEMP fish sampling program was reduced to three weeks during the open water season (continued in 2021); however, unlike in previous years where fishing was conducted alongside other MEEMP program components over the four- to five-week program, a dedicated fish sampling team was created to increase efficiency and catch opportunities in the limited available open water season. Additionally in 2020, trawling was trialled as a fishing method in Milne Port to improve detection of rarely sampled fish species (i.e., bottom-associated taxa); trawling has been continued since 2021. Changes were also made to angling efforts in 2020 to target specific areas for species of interest (e.g., Arctic Char [*Salvelinus alpinus*] and Fourhorn Sculpin [*Myoxocephalus quadricornis*]) and to better support the objectives of the MEEMP Fish Health program (see Chapter 7.0 Fish Health and Tissue Chemistry). In 2021, longlining was trialled as a fishing method in Milne Port to improve capture efficiency and community detection of deeper benthic species; however, as no fish were caught, the method was discontinued for 2022.

In 2021, a brief reconnaissance survey was undertaken near the Tugaat River estuary to identify a suitable reference area for the fish health and tissue chemistry component of the MEEMP. Exploratory fishing efforts were continued in 2022 in two general locations: southwest of the Tugaat River outflow, approximately 15 km northeast of Milne Port, and on the northern shore of the mouth of Koluktoo Bay, approximately 23 km northeast of Milne Port. Exploratory fishing continued in 2023 at these two locations (reported in Chapter 7.0 – Fish Health and Tissue Chemistry).

In 2022, CPUE calculations were revised for two fishing methods (hoop nets and Fukui traps) to better account for field variability. Previously, CPUE was assessed for these methods as number of fish per 24 hours of effort per trap. For the 2022 and 2023 reports, CPUE metrics were modified to the number of fish per hour of effort per trap. Data from 2020 and 2021 were recalculated with the modified CPUE calculations.

Table 6-1: MEEMP Fish Capture Methods per Year (2010-2023)

Sampling Method	2010	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023

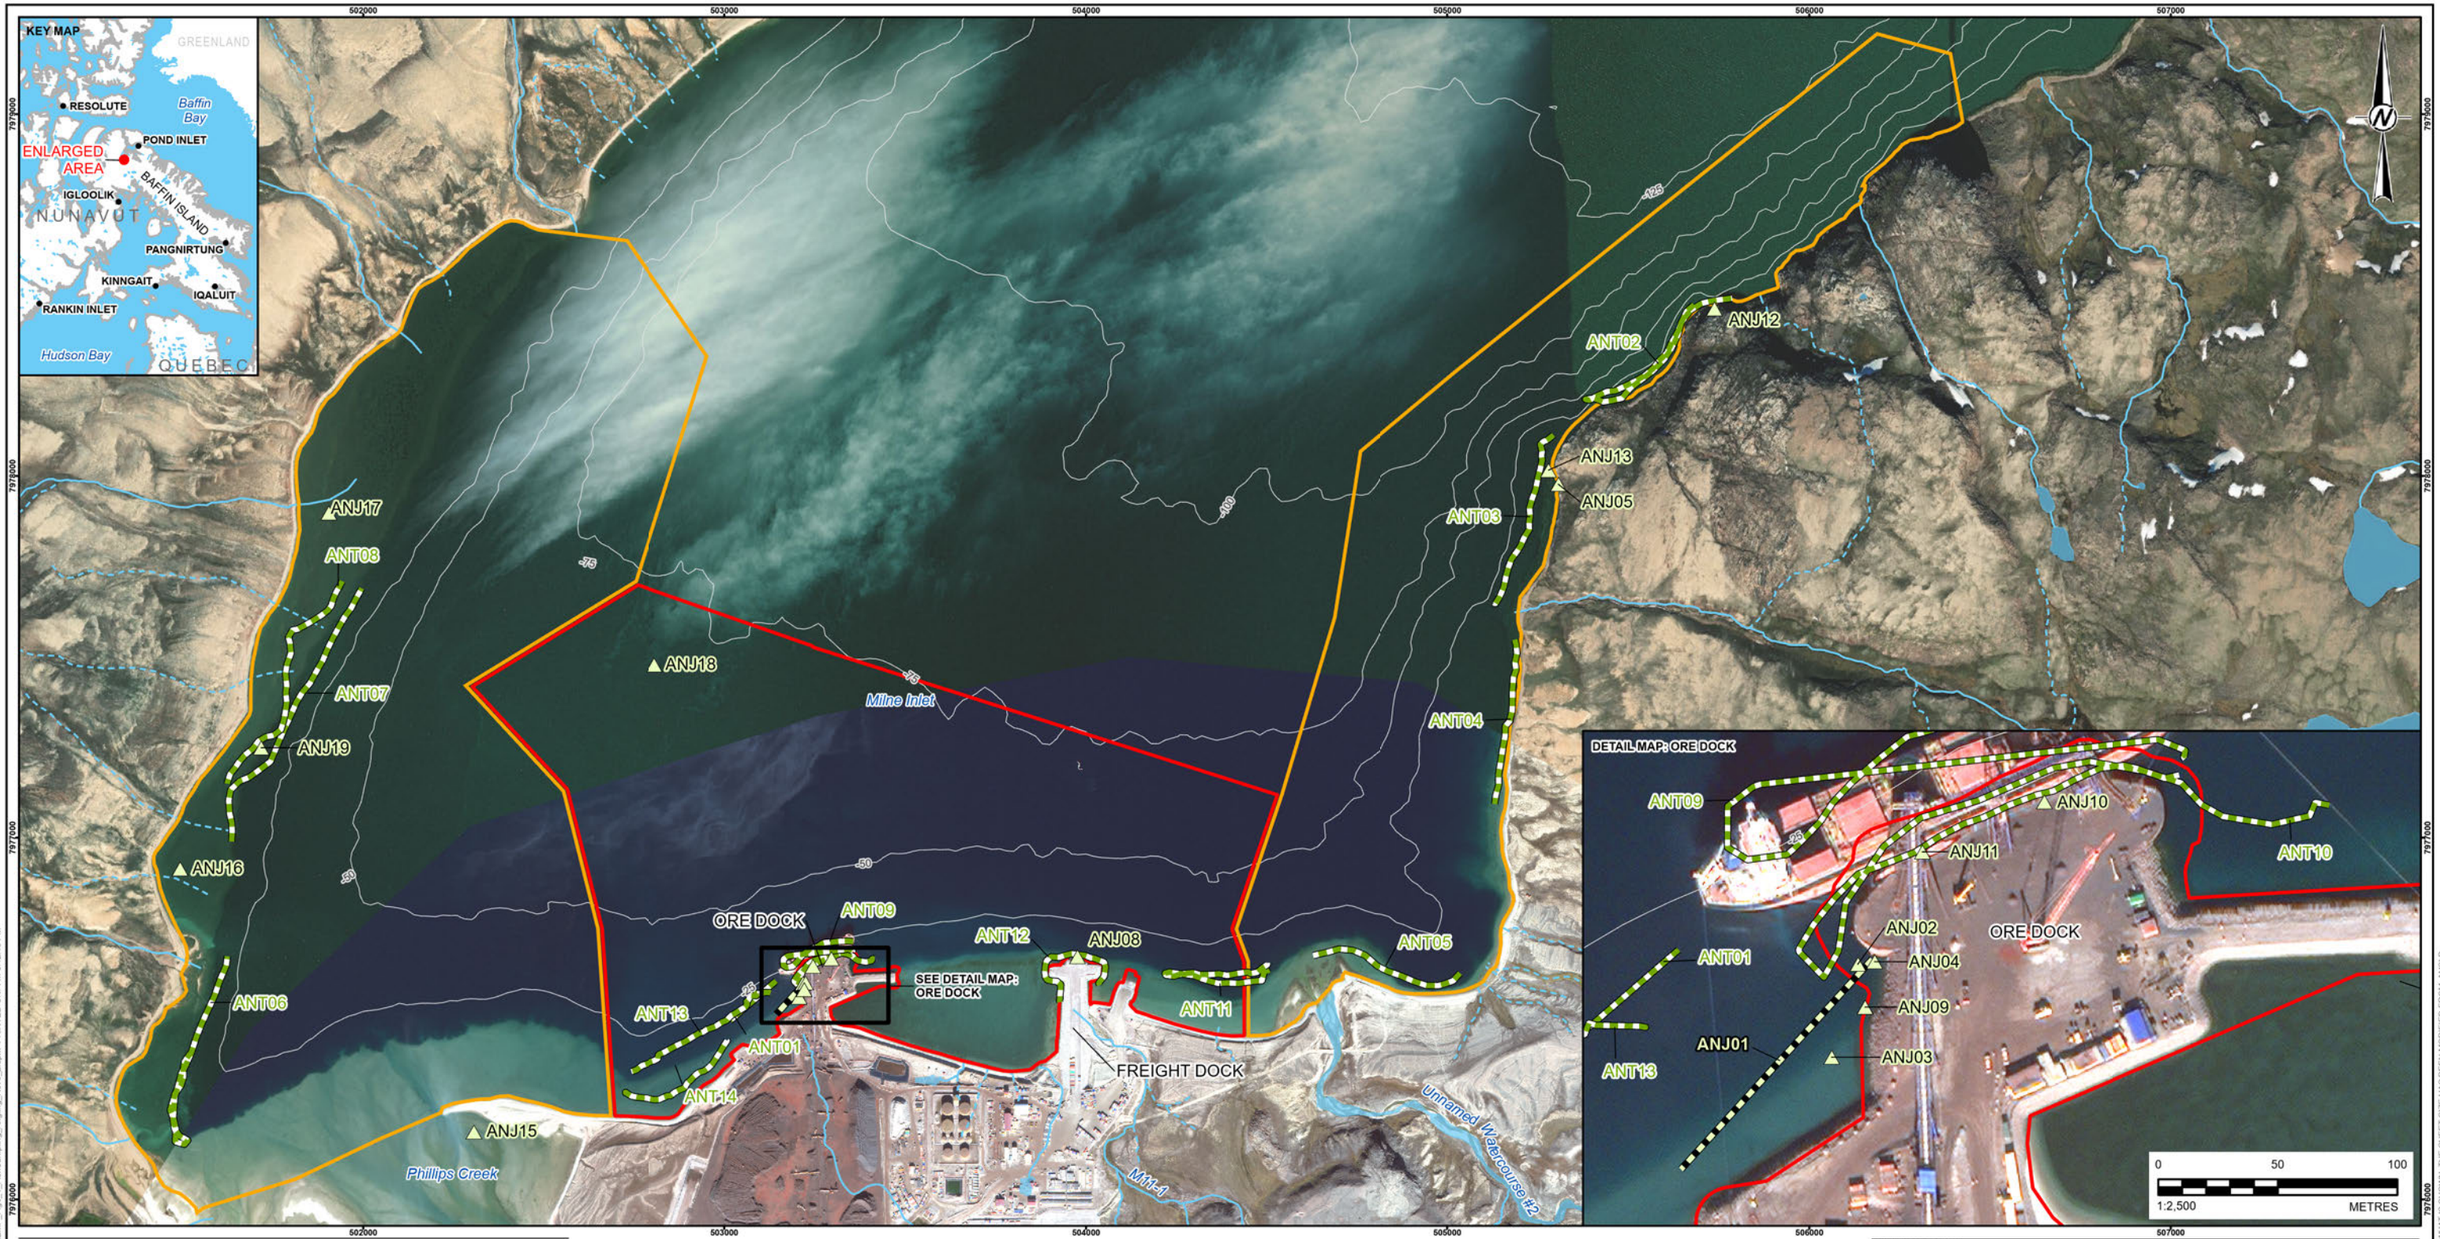
Trawling									√*	√	√	√



*Limited sampling events to trial the method.

6.3.1 Modifications to the Program (2023)

In 2023, fishing methods were modified by decreasing the number of Fukui traps within sets from three to one. This adjustment aimed to synchronize Fukui trap deployment hours with those of hoop nets, facilitating a more accurate comparison between fish sampling methods and their respective results in the fourth trial year. Increased fishing efforts (e.g., angling (jigging and trolling), Fukui traps, gill nets, and hoop nets) on the western shore near Phillips Creek were conducted in 2023 to further characterize the marine fish community in Milne Port.

Continued exploratory fishing to identify a suitable reference area for the MEEMP fish health sampling program was conducted over three days in 2023 on the northern shore of the mouth of Koluktoo Bay, approximately 23 km northeast of Milne Port. Exploratory fishing results, including locations for the 2023 fish sampling undertaken to identify a favourable reference site, are presented in Chapter 7.0 (Fish Health and Tissue Chemistry).

Figure 6-1 through Figure 6-5 illustrate the 2023 deployment locations for each fishing method and identify the boundaries of the two fishing areas in Milne Port. Figures 1 through 5 in Appendix 6D illustrate the 2020 to 2023 deployment locations for each fishing method.

6.3.2 Endpoints

CPUE is the primary metric used for characterization of the fish catch data, in addition to total number of fish caught, taxa richness, and relative abundance of taxa. Comparison using these metrics is only meaningful within a fishing method and this report does not make statistical comparisons between methods. Statistical comparisons of CPUE data within methods, from 2020 to 2023 and contrasting the two fishing areas (DPF and IPF), were completed for this report. A statistical analysis of CPUE over the course of the entire MEEMP program (2015 to 2023) was not feasible due to the limited sample sizes and inconsistent fishing effort data for sampling events conducted prior to 2020.

6.4 Materials and Methods

6.4.1 Field Methodology

Fish sampling was conducted in the Milne Port area from 28 July to 14 August 2023 using both active (angling [jigging and trolling], gill net, and trawling) and passive (Fukui trap and hoop net) capture methods (Figure 6-1 to Figure 6-5). Fish sampling locations were consistent with those used in previous years, including exploratory reference site sampling in Koluktoo Bay for the fish health program. Fishing effort in 2023 occurred over a three-week period during the open-water season. When possible, fish species were identified in the field and released alive. All fish mortalities were retained and processed as described in Chapter 7.0 (Fish Health and Tissue Chemistry).

6.4.1.1 Permitting

The following scientific data collection permits were obtained prior to the start of the 2023 fish sampling program:

- Fisheries and Oceans Canada (DFO) Licence to Fish for Scientific Purposes Permit # S-23/24-1027-NU-A1
- DFO Animal Use Protocol Permit # OPA-ACC-2023-05
- Nunavut Research Institute (NRI) Scientific Research Licence # 02 012 23R-M

Copies of permits are provided in Appendix 6A.

6.4.1.2 Fishing Areas

Recognizing that the marine fish community may differ across the Milne Port area and differences may or may not stem from potential Project-related effects, two distinct Fishing Areas (FAs) were identified for Milne Port; one encompassing waters directly in or adjacent to the terminal infrastructure footprint (Direct Project Footprint area; DPF) and one encompassing waters outside (west and east) of the terminal infrastructure footprint (Indirect Project Footprint; IPF). The two FAs reflected different exposure levels relative to terminal operations and marine berthing activities. The integration of FAs in the study design provided an opportunity to better characterize variability in Milne Port area fish communities and standardize sampling locations among years. Coverage and effort across the FAs were determined, in part, by the effectiveness of a particular method in characterizing the fish community within an FA, consequently each FA may have included a range of sampling efforts and methods. A description of the FAs is provided in Table 6-2 and their spatial arrangement is shown in Figure 6-1 to Figure 6-5.

Table 6-2: Fishing Areas (FAs) of Milne Port

Fishing Area	Area (ha)	Description
Direct Project Footprint (DPF)	192.14	The Direct Project Footprint FA (DPF) includes the immediate Area of Influence adjacent to Project infrastructure, and includes shoreline in the vicinity of the Ore Dock, Ore Pile, Freight dock, and Fuel Farm. The DPF is also an area of relatively high marine traffic compared to the Indirect Project Footprint (see below). Habitat in the DPF is characterized by mixed (sand/gravel to cobble/boulder)[1] shoreline including coarse rock offsetting habitat along the Ore Dock and Freight Dock. The DPF FA extends 1.38 km from shore at its western boundary, and 0.98 km from shore at its eastern boundary.
Indirect Project Footprint (IPF)	405.64	The Indirect Project Footprint[2] FA (IPF) includes areas along the shorelines to the east and west of the DPF, outside of the immediate Area of Influence. The IPF includes the mouth of Philips Creek, which is characterized by soft substrate (sand and gravel) and brackish water, as well as the shoreline to the east of the DPF, which is also characterized by brackish water due to input from Unnamed Watercourse #2, as well as substrate ranging from soft sand to mixed gravel and cobble. The IPF FA extends 2.63 km from shore at the mouth of Philips Creek at its western boundary, and 2.77 km from the southern shore of Milne Inlet at its western boundary.

[1] See Chapters 3.0 and 5.0 for definitions of substrate size categories.

[2] Note: IPF does not include fishing areas around Tugaat River or Koluktoo Bay. See Chapter 7.0 (Fish Health and Tissue Chemistry) for more information on reference area fish capture results.

6.4.1.3 Fishing Methods

A total of 82 fishing efforts (i.e., sampling events) comprising six methodologies were completed in Milne Port in 2023. A summary of the fishing efforts is presented in Table 6-3 with summaries of each method found in Sections 6.4.1.3.1 to 6.4.1.3.5. Full details for each fishing sampling effort can be found in Appendix 6B.

Table 6-3: Summary of 2023 Fish Sampling Efforts in Milne Port

Fishing Method	Area	Number of Fishing Efforts (N)	Total Effort (hours)
Angling – Jigging	DPF	8	3.6
	IPF	8	4.6
Angling – Trolling	DPF	7	1.7
	IPF	7	2.2
Fukui Trap[1]	DPF	7	388.7
	IPF	7	322.8
Gill Net	DPF	10	26.2
	IPF	10	23.9
Hoop Net	DPF	7	391.7
	IPF	7	328.9
Trawling	DPF	2	0.8
	IPF	2	0.9

[1] Unlike in previous years when sets were comprised of three traps, sets in 2023 were only comprised of one trap each to better align with hoop net deployment hours.

6.4.1.3.1 Angling (Jigging and Trolling)

Angling (jigging and trolling) was conducted between 28 July and 13 August 2023 to characterize the demersal and pelagic fish community in Milne Port (Appendix 6B). Jigging occurred from a stationary position or during vessel movement with two to three rods and lines deployed from the field vessel (Appendix 6C – Photo 1). Hooks or spoon lures were allowed to hit the bottom, then flicked upward to attract bottom fish. For trolling, lines with lures were cast over the side of the field vessel and spooled in towards the vessel to attract pelagic fish (Appendix 6C – Photo 2).

A total of 30 angling events (fishing efforts) were undertaken across the two FAs with 15 events in each FA (Table 6-3; Figure 6-1). The total effort for both angling methods for Milne Port was 33.84 rod-hours. The duration of sampling was activity-dependent, with jigging ranging between 0.53 and 7.00 rod-hours (N=15) and trolling ranging between 0.33 and 1.25 rod-hours (N=15). Start and end coordinates of angling efforts were recorded using a Garmin GPS (global positioning system) and logged in a field notebook.

6.4.1.3.2 Fukui Traps

Fukui traps were used to sample demersal fish in nearshore habitat at Milne Port between 29 July and 14 August 2023 (Appendix 6B). Each Fukui trap event, referred to as a ‘set’, consisted of a single trap measuring 61 cm x 46 cm x 20 cm, with 1.25 cm stretch mesh, and equipped with a bait container. Since 2019, Fukui traps have been deployed using the ‘sinker’ method described in Bergshoeff et al. (2019), following a recommendation made by the MEWG (QIA; 2018 MEEMP/AIS report comments; M-23042019; M-21062019). Traps were baited with Arctic Char (accidental mortalities, see Chapter 7.0 Fish Health and Tissue Chemistry for details) prior to being deployed for two to three days at each station. Traps were checked every 1-2 days and bait containers were refilled, if necessary, prior to redeployment. Fishing locations and depths were recorded using a Garmin GPS and Hummingbird depth sounder and logged in a field notebook.

A total of 14 Fukui trap sampling events were undertaken with seven sets in each of the FAs (Table 6-3; Figure 6-2). Deployment time was calculated by trap-hours (i.e., number of traps deployed multiplied by time deployed) and ranged from 25.47 to 73.00 trap-hours, with a mean deployment time of 50.80 trap-hours. Due to consistently low CPUE in Fukui traps in all years of the program, hoop nets (Section 6.4.1.3.4) were used starting in 2020 to assess their potential as a replacement for Fukui traps. Use of Fukui traps has continued through 2023 to meet existing commitments to the MEWG to continue both methodologies for a minimum of three years to allow for a comparison between fish sampling methods and results.

6.4.1.3.3 Gill Nets

Standardized monofilament gill nets were deployed between 28 July to 13 August 2023 to sample shallow (i.e., subtidal areas to a maximum depth of -15 m CD [chart datum]) for characterization of pelagic fish communities present in the Milne Port area. The gill net sampling events were divided evenly between the two FAs (Table 6-3; Figure 6-3). Each gill net consisted of six panels with each panel measuring 15.2 m in length and 2.4 m in width, with panel mesh sizes (stretch) of 2.5 cm, 3.8 cm, 5.1 cm, 6.4 cm, 7.6 cm, and 10.2 cm. The gill nets were deployed in a shore-perpendicular orientation (smallest mesh size closest to shore) and were either suspended just below the water surface or were weighted to run along the seabed (Appendix 6C – Photo 3). Nets were examined for fish presence at least once every two hours for the duration of deployment (soak duration was at most four hours). Sampling locations were recorded using a Garmin GPS and logged in a field notebook.

A total of ten gill net sets in each of the two FA were performed from 28 July and 13 August 2023 (Appendix 6B). Total soak times ranged from 0.92 hour to 4.92 hours, with an average soak time of 2.51 hours. End times of efforts were recorded as the time when the net is fully out of the water. The planned maximum soak time of gill nets was four hours, but this was exceeded in one case due to large numbers (over 80 fish) captured in one set, requiring extra handling time to extract each fish safely. Total soak time for all gill net sampling combined was 50.12 hours.

6.4.1.3.4 Hoop Nets

Hoop nets were used to sample demersal fish in nearshore habitat at Milne Port between 29 July and 14 August 2023. Sampling was conducted using a single 5 m-long dual-chamber hoop net with 32 mm (stretch) mesh (Appendix 6C – Photo 4). Orientation of the hoop nets varied by deployment type. Shore-based nets were set in the subtidal zone during low tide with the wing panels running from a water depth of +2 m CD to -1 m CD. Nets were checked every 1-2 days after deployment. Shore-based nets were either placed ‘perpendicular’, so the 1 m-diameter mouth was perpendicular to the shore and the 10 m-length wing panels were oriented in a wide V-shape extending towards shore, targeting fish moving through the subtidal, or ‘parallel’, so the 5 m-long body of the net was parallel to shore targeting fish moving in and out of sources of freshwater input. The end of the hoop net wings and body were weighted to lay flat on the seabed, targeting demersal species.

A total of 14 hoop net sampling events (referred to as ‘sets’ consisting of a single net per set) were undertaken with seven sets in each of the two FAs (Table 6-3, Figure 6-4). Fishing locations were recorded using a Garmin GPS and logged in a field notebook. Total sampling effort was 720.58 hours with an average sampling effort per net of 51.5 hours (Appendix 6B).

6.4.1.3.5 Trawling

Trawl sampling, conducted on 2 and 3 August 2023, consisted of towing an otter trawl from a vessel for a set time (between 0.40 and 0.50 hours) and trawl distance (between 530 and 910 m). The otter trawl comprised a cone shaped net composed of a 4.9 m wide diameter mouth held open by two wooden doors on either side of the opening (Appendix 6C – Photo 5). The front section of the net was composed of 38 mm stretched nylon mesh. The rear of the net (cod end) was composed of 32 mm stretched mesh. The otter trawl was deployed from the vessel’s hydraulic A-frame system, with the net towed slowly off the bow while the vessel slowly reversed at a speed of one knot. Once the net reached the seafloor, it was raised slightly (to ~2 to 3 m above bottom) to minimize impacts on the sea floor and to target benthic/demersal fish species. Sampling locations were selected based on water depth and bottom morphology using bathymetric charts. Sample contours ranged from 30 to 52 m in depth. Start and end waypoints for otter trawl sampling were recorded using the onboard navigation system (Raymarine Axiom Hybrid Touch Pro with Navionics+ Bundle) and logged in a field notebook (Appendix 6B).

In 2023, four trawl sampling events were conducted in the Milne Port area, two in each FA (Table 6-3; Figure 6-5).

6.4.1.4 Fish Health Reference Site – Exploratory Fishing

On 1, 8, and 12 August 2023, exploratory fishing was conducted at two sites on the northern edge of Koluktoo Bay to assess area suitability as a potential fish health program reference site, expanding upon exploratory efforts in 2021 and 2022 during which no favourable site was identified. Fishing efforts included gill netting and angling (jigging). Further details of each exploratory site and fishing effort are presented in Chapter 7.0 (Fish Health and Tissue Chemistry).

6.4.2 Data Analysis

Consistent with previous years, figures were prepared for visualization of the fish catch data by sampling method. Descriptive summary statistics (e.g., mean, standard deviation [SD], CPUE) were also used to compare total catch and catch data among common taxa, sampling method and survey year. To remain consistent with the 2020 to 2022 reports, descriptive summary statistics were also provided for length and weight data in Appendix 6D – Tables 1 and 2.

Catch data, specifically CPUE, for each fishing method were reported according to the units in Table 6-4.

Table 6-4: Catch Per Unit Effort Units for each Fishing Method

Fishing Method	Unit	Description
Angling (Jigging/Trolling)	Fish*hr^{-1}*rods^{-1}	Relative to 1 hour of effort and the number of rods
Fukui Trap	Fish*hr^{-1}*traps^{-1}	Relative to 1 hour of deployment and the number of traps
Gill Net	Fish*hr^{-1}*100 m^{-1}	Relative to 1 hour of effort and for the length of the net adjusted via correction factor to 100 m
Hoop Net	Fish/hr	Relative to 1 hour of deployment
Longlining	Fish*hr^{-1}*rods^{-1}	Relative to 1 hour of deployment and the number of hooks per line
Seine Net	Fish/haul area	Relative to total area covered (m^2)
Trawling	Fish/hr	Relative to 1 hour of deployment

As was done in 2022, longlining, seine net, and trawling were excluded from statistical analysis as longlining was conducted only in 2021, seine netting was conducted only in 2020, and trawling in 2020 was limited to a single effort to trial the method. Sample size of trawling efforts was low (1-2 efforts per FA per year) in all years 2021-2023, as the purpose of trawling in this study was to augment the biodiversity of fish captures within the Port area rather than to conduct statistically comparable sampling.

For angling (jigging and trolling), Fukui trap, gill net, and hoop net datasets, trends in CPUE as a function of sampling year and sampling location (i.e., FA) were assessed using a generalized linear model with a negative binomial distribution. The response variable in the model was the number of fish caught, and to account for differences in effort, each model used an offset that depended on the type of sampling effort; for angling (both jigging and trolling), the offset was calculated by multiplying the number of rods by the duration of fishing period. For Fukui traps, the offset was calculated by multiplying the number of traps in each cluster by the duration of trap set. For gill nets, the offset was calculated by multiplying the duration of set period by the gill net correction factor, which standardized fishing to 100 m of net. For hoop nets, the offset was simply the duration of set period. The

models included the main effects of year (as a categorical variable) and sampling location (i.e., FA), as well as the interaction between the two. Trolling was only conducted once in 2021, in the IPF; therefore, this single data point was removed from data analysis, resulting in only 2020 and 2022 data being analysed for the trolling catch dataset.

A significance level (α) of 0.05 was used to interpret results. If the interaction between year and sampling area was significant, or if the interaction was not significant but the main effect of year was significant, multiple comparisons with familywise error corrections were used to assess specific differences between individual sampling years (except for trolling where only two years were available) or between locations within year (for a significant interaction term). If the interaction was not significant but the main effect of location was statistically significant, a multiple comparison was not performed, since there were only two sampling locations, and hence a significant main effect of location indicated a significant difference between the locations. *P*-values <0.05 were considered to indicate significance between groups. Analyses were conducted using R software version 4.3.2 (R Core Team 2023).

Power Analysis

A power analysis was conducted using the 2020 to 2023 data to estimate the sample size needed to detect Project-related change based on levels of observed variability between FAs. The power analysis was conducted to evaluate the number of efforts required to achieve 80% statistical power to detect 20%, 30% and 40% reductions in CPUE in the DPF relative to the IPF in 2023 (for models with a significant interaction between year and area) or in 2023 relative to 2022 (for models without a significant interaction). A full description of the power analysis methodology is provided in Appendix 6E.

6.4.3 Field Quality Assurance and Quality Control

Quality assurance and quality control (QA/QC) measures for quantitative and qualitative data collected during fishing surveys included the following:

- Prior to fishing activities, field team members were briefed on sampling protocols and each individual's role in data collection. Fishing methodologies were standardized to minimize the introduction of sampling error during sample collection.
- Nets and traps were cleaned between efforts and checked for breakages or failures to maintain consistency in efforts. Broken nets and traps were repaired or replaced before being put back into use.
- Field notes were taken during surveys using prepared field sheets to provide a comprehensive data collection process and a consistent record of sampling effort. A second team member reviewed data from field sheets and entered them into a spreadsheet while checking for inconsistencies or missing information. A third team member reviewed the entered data for inconsistencies and completeness.
- Scans of the field datasheets and GPS waypoints were saved to a laptop computer and external hard drive at the end of each workday. Fish were identified to lowest practicable level (species, where possible). Any identification that was questionable in the field was verified using fish field guides. Fish that could not be identified to species level in the field were retained for subsequent identification by Biologica Environmental Services Ltd., an accredited taxonomic laboratory.

6.5 Results

Details of fish catch data from 2020 to 2023 are presented in Appendix 6B and shown in figures in Appendix 6D. Field photographs are presented in Appendix 6C. Supplemental results figures and tables are provided in Appendix 6D, and power analysis to evaluate the number of efforts required to detect reduction in CPUE in the DPF of 20%, 30% and 40% compared to the IPF, with 80% statistical power, is detailed in Appendix 6E.

6.5.1 2023 Summary

A total of 422 fish representing 12 known taxa were recorded in the DPF and IPF from 82 fishing efforts using a combination of methods during the 2023 open water survey season in Milne Port (Table 6-5; Table 6-6). Similar to previous sampling years (SEM 2016, 2017; Golder 2018, 2019, 2020, 2021, 2022), Fourhorn Sculpin (75%; Appendix 6C – Photo 6) and Arctic Char (12% of catch; Appendix 6C – Photo 7) were the two most common fish species captured (all sampling methods combined), comprising 87% of the total catch (all methods combined) in 2023 (Table 6-5). The remaining 13% of the total catch was composed of: Shorthorn Sculpin (*Myoxocephalus scorpius*, 4%; Appendix 6C – Photo 8); Arctic Staghorn Sculpin (*Gymnocanthus tricuspis*, 4%; Appendix 6C – Photo 9); Ribbed Sculpin (*Triglops pingelii*, 2%; Appendix 6C – Photo 10); Pacific Cod (*Gadus macrocephalus*[1], 1%; Appendix 6C – Photo 11); Arctic Alligatorfish (*Aspidophoroides olrikii*, 1%; Appendix 6C – Photo 12); Arctic Sculpin (*Myoxocephalus scorpioides*, <1%; Appendix 6C – Photo 13); Spatulate Sculpin (*Icelus spatula*; <1%; Appendix 6C – Photo 14); and single instances of juvenile Polar Cod (*Boreogadus saida*; <1%), Saddled Eelpout (*Lycodes mucosus*; <1%), and a juvenile cod identified only to genus (*Gadus* sp.; <1%; Appendix 6C – Photo 15; Table 6-5). One species was captured for the first time during fishing efforts in Milne Port: a single Atlantic Spiny Lumpsucker (*Eumicrotremus spinosus*; <1%; Appendix 6C – Photo 16), but was visually detected in Milne Port during the freight dock offsetting habitat surveys in 2021 (Golder 2022).

Table 6-5: Total Number of Fish Caught by Taxon and Fishing Method (2023)

Taxa	Angling - Jigging		Angling - Trolling		Fukui Trap		Gill Net		Hoop Net		Trawling		Total
	DFP	IPF	DPF	IPF	DPF	IPF	DFP	IPF	DFP	IPF	DFP	IPF

Unidentified Cod	0	0	0	0	0	0	0	0	0	0	0	1	**1**
Total	**45**	**24**	**0**	**3**	**1**	**3**	**214**	**59**	**36**	**4**	**13**	**20**	**422**

[1] Taxonomic nomenclature changes have adopted Greenland Cod under the name Pacific Cod (FishBase 2023; GBIF 2023).

[1] Recent taxonomic changes to the genus *Gadus* have combined species *G. ogac* (Greenland Cod) and *G. macrocephalus* (Pacific or Alaska Cod) under the umbrella term *G. macrocephalus* (FishBase 2023; GBIF 2023). A universal edit has been made to change Greenland cod (*G. ogac*) to Pacific Cod (*G. macrocephalus*).

Unlike in previous years, trawling had the highest taxa diversity of captured fish (six known taxa, not counting the juvenile *Gadus* sp.) but overall low numbers of each taxon (Table 6-5). None of the taxa captured by the trawling were represented in any other sampling method. Jigging and gill nets captured four taxa each, but 72% and 82%, respectively, of the fish recorded were Fourhorn Sculpin. Fukui traps captured three taxa, including a juvenile Polar Cod. Trolling and hoop nets each captured two taxa: Fourhorn and Shorthorn Sculpin (Table 6-5).

As in previous years, gill nets captured higher numbers of fish than any other method in 2023, with 214 fish in the DPF and 59 fish in the IPF (Table 6-6). Hoop nets and trawling methods captured fewer than 60 fish each, with hoop nets having higher total catch within the DPF than IPF but the opposite seen for trawling total catch. Trolling and Fukui traps were the least successful fishing methods utilized in 2023, capturing only three and four fish in total, respectively (Table 6-6).

Table 6-6: Total Number of Efforts and Fish Captured by Fishing Method and Fishing Area (Direct Project Footprint [DPF] and Indirect Project Footprint [IDF]) (2023)

Fishing Method	Number of Efforts		Total Number of Fish Captured	
	DPF	IPF	DPF	IPF
Angling - Jigging	8	8	45	24
Angling - Trolling	7	7	0	3
Fukui Trap	7	7	1	3
Gill Net	10	10	214	59
Hoop Net	7	7	36	4
Trawling	2	2	13	20
Total	**41**	**41**	**309**	**113**

Mean CPUE of the three dominant taxa captured (Arctic Char, Fourhorn Sculpin, and Shorthorn Sculpin) was low for all fishing methods with large variability in CPUE rates (Table 6-7). Of these three species, Fourhorn Sculpin (and Arctic Char, opportunistically) were assessed as indicators of fish health in Milne Inlet (see Chapter 7.0 Fish Health and Tissue Chemistry); examining their catch rates by gear type demonstrated they were most effectively captured using different methods. Arctic Char were most effectively caught by gill nets with a mean CPUE of 0.99±1.39 fish*hr^{-1}*100 m^{-1} (Table 6-7). Jigging also captured a single Arctic Char with a CPUE value of 0.05±0.19 fish*hr^{-1}*rod^{-1} (Table 6-7). Fourhorn Sculpin were most efficiently caught via jigging with a mean CPUE of 1.83±3.49 fish*hr^{-1}*rod^{-1} and via gill nets (mean CPUE = 3.77±5.36 fish*hr^{-1}*100 m^{-1}; Table 6-7). CPUE was low for trolling, Fukui traps, and hoop nets, with mean CPUE <0.20 for all taxa. Trawling captured fish that were not represented in any other fishing method, with CPUE rates of 3.14 ± 6.74 fish/hr for sculpins other than the dominant taxa (largely driven by Arctic Staghorn Sculpin) and 0.38±1.02 fish/hr for non-sculpins (driven by Arctic Alligatorfish; Table 6-7).

Table 6-7: Catch Per Unit Effort Summary Statistics (Mean±SD across sites) by Taxon and Fishing Method (2023)

Taxa[1]	Angling – Jigging (fish*hr^{-1}*rod^{-1})	Angling – Trolling (fish*hr^{-1}*rod^{-1})	Fukui Trap (fish*hr^{-1}*trap^{-1})	Gill Net (fish*hr^{-1}*100m^{-1})	Hoop Net (fish/hr)	Trawling (fish/hr)
Arctic Char	0.05±0.19	0.00±0.00	0.00±0.00	0.99±1.39	0.00±0.00	0.00±0.00
Fourhorn Sculpin	1.83±3.49	0.10±0.36	<0.01±0.01	3.77±5.60	0.06±0.13	0.00±0.00
Pacific Cod	0.27±0.64	0.00±0.00	0.00±0.00	0.00±0.00	0.00±0.00	0.00±0.00
Shorthorn Sculpin	0.35±1.01	0.14±0.53	0.00±0.00	0.01±0.06	<0.01±<0.01	0.00±0.00
Other Sculpins	0.00±0.00	0.00±0.00	<0.01±<0.01	<0.01±0.02	0.00±0.00	15.70±14.57
Other Fish	0.00±0.00	0.00±0.00	<0.01±<0.01	0.00±0.00	0.00±0.00	4.13±5.36
All Fish	**2.50±3.50**	**0.24±0.62**	**0.01±0.01**	**4.78±5.46**	**0.06±0.14**	**19.83±19.04**

[1] Fish taxa were grouped based on relative abundance percentages from 2020 to 2023 catch data. Taxa with abundances <5% were grouped as follows: other sculpin (Arctic Sculpin, Arctic Staghorn Sculpin, Ribbed Sculpin, Spatulate Sculpin) and other fish (Arctic Alligatorfish, Atlantic Spiny Lumpsucker, Polar Cod, Saddled Eelpout, Unidentified Cod). Pacific cod (*G. macrocephalus*) is the new taxonomically accepted name of Greenland Cod (*G. ogac*).

6.5.2 Interannual Comparisons

6.5.2.1 Fish Community

From 2020 to 2023, a total of 2,361 fish were caught within Milne Inlet during open-water surveys (Appendix 6B, Appendix 6D – Tables 3 and 4). The dominant fish taxon caught over the three-year period was Fourhorn Sculpin (55%) followed by Arctic Char (17%) across all methods combined.

Gear-specific relative abundances of fish species across years (2020 to 2023) remained fairly consistent (Table 6-8; Figure 6-6). Angling-jigging predominantly caught Fourhorn Sculpin, Shorthorn Sculpin and Pacific Cod (average relative abundance 2020–2023 = 68%, 15%, and 13%, respectively) while angling-trolling predominantly caught Shorthorn Sculpin and Fourhorn Sculpin (average relative abundance 2020–2023 = 66% and 26%, respectively; Table 6-8; Figure 6-6). Relative abundances of fishes captured by angling-trolling fluctuated among years with the number of efforts and associated catch; between 2020 and 2021 seven efforts were completed with only a single fish caught, while in 2022 seven[2] efforts captured 16 fish, and in 2023 eight efforts captured three fish (Appendix 6B).

Fukui traps caught mainly Fourhorn Sculpin and non-dominant sculpin taxa (e.g., Arctic Sculpin) (average relative abundance 2020–2023 = 42% and 37%, respectively; Table 6-8; Figure 6-6). Fukui trap catches in 2023 were similar to that in 2022 compared to 2020 and 2021 with increased relative abundances of non-dominant fish (e.g., Polar Cod in 2023 and eelpouts in 2022); however, unlike in 2022, no Shorthorn Sculpin or Pacific Cod were captured via Fukui traps (Table 6-8). Hoop nets almost exclusively caught Fourhorn Sculpin (average relative abundance 2020–2023 = 95%; Table 6-8; Figure 6-6).

[2] One angling-jigging effort was erroneously labelled as angling-trolling in the 2022 report. The error has been corrected in the 2023 report.

Gill nets almost exclusively caught Fourhorn Sculpin and Arctic Char (average relative abundance 2020–2023 = 57% and 38% of gill net captures, respectively; Table 6-8; Figure 6-6). In 2023, the relative abundances of Arctic Char and Fourhorn Sculpin were 18% and 82%, respectively (Table 6-8). Longlines, only utilized in 2021, did not catch any fish. Seine nets, only utilized in 2020, mainly captured juvenile unidentified sculpins (61%) and Fourhorn Sculpin (30%; Table 6-8; Figure 6-6). From 2020-2023, trawling consistently caught only non-dominant sculpin species (e.g., Arctic Staghorn Sculpin, Ribbed Sculpin, Spatulate Sculpin, and unidentified sculpins) and several rarely caught fish taxa (e.g., Atlantic Poacher, Atlantic Spiny Lumpsucker, Polar Cod, unidentified cod, and unidentified snailfish; average relative abundance 2020–2023 = 64% and 36%, respectively; Table 6-8; Figure 6-6).

Table 6-8: Relative Abundances of Grouped Taxa by Fishing Method and Year (2020-2023)

Method[1]	Year	Arctic Char	Fourhorn Sculpin	Pacific Cod	Shorthorn Sculpin	Other Sculpin	Other Fish
Angling - Jigging	**2020**	1%	58%	22%	18%	2%	0%

	2022	0%	0%	0%	0%	79%	21%
	2023	0%	0%	0%	0%	79%	21%

Note: Pacific Cod (*G. macrocephalus*) is the new taxonomically accepted name of Greenland Cod (*G. ogac*). Grey highlighting indicated relative abundances >40%. Fish taxa were grouped based on relative abundance percentages from 2020 to 2023 catch data. Taxa with abundances <5% were grouped as follows: other sculpins (Arctic Sculpin, Arctic Staghorn Sculpin, Ribbed Sculpin, Spatulate Sculpin, and unidentified sculpins) and other fishes (Arctic Alligatorfish, Arctic Cod, Atlantic Poacher, Atlantic Spiny Lumpsucker, Fourline Snakeblenny, Halfbarred Pout, Northern Sand Lance, Polar Cod, Saddled Eelpout, unidentified cods, and unidentified snailfish).

[1] Longlining was discontinued in 2022 as no fish were caught during any effort in 2021.

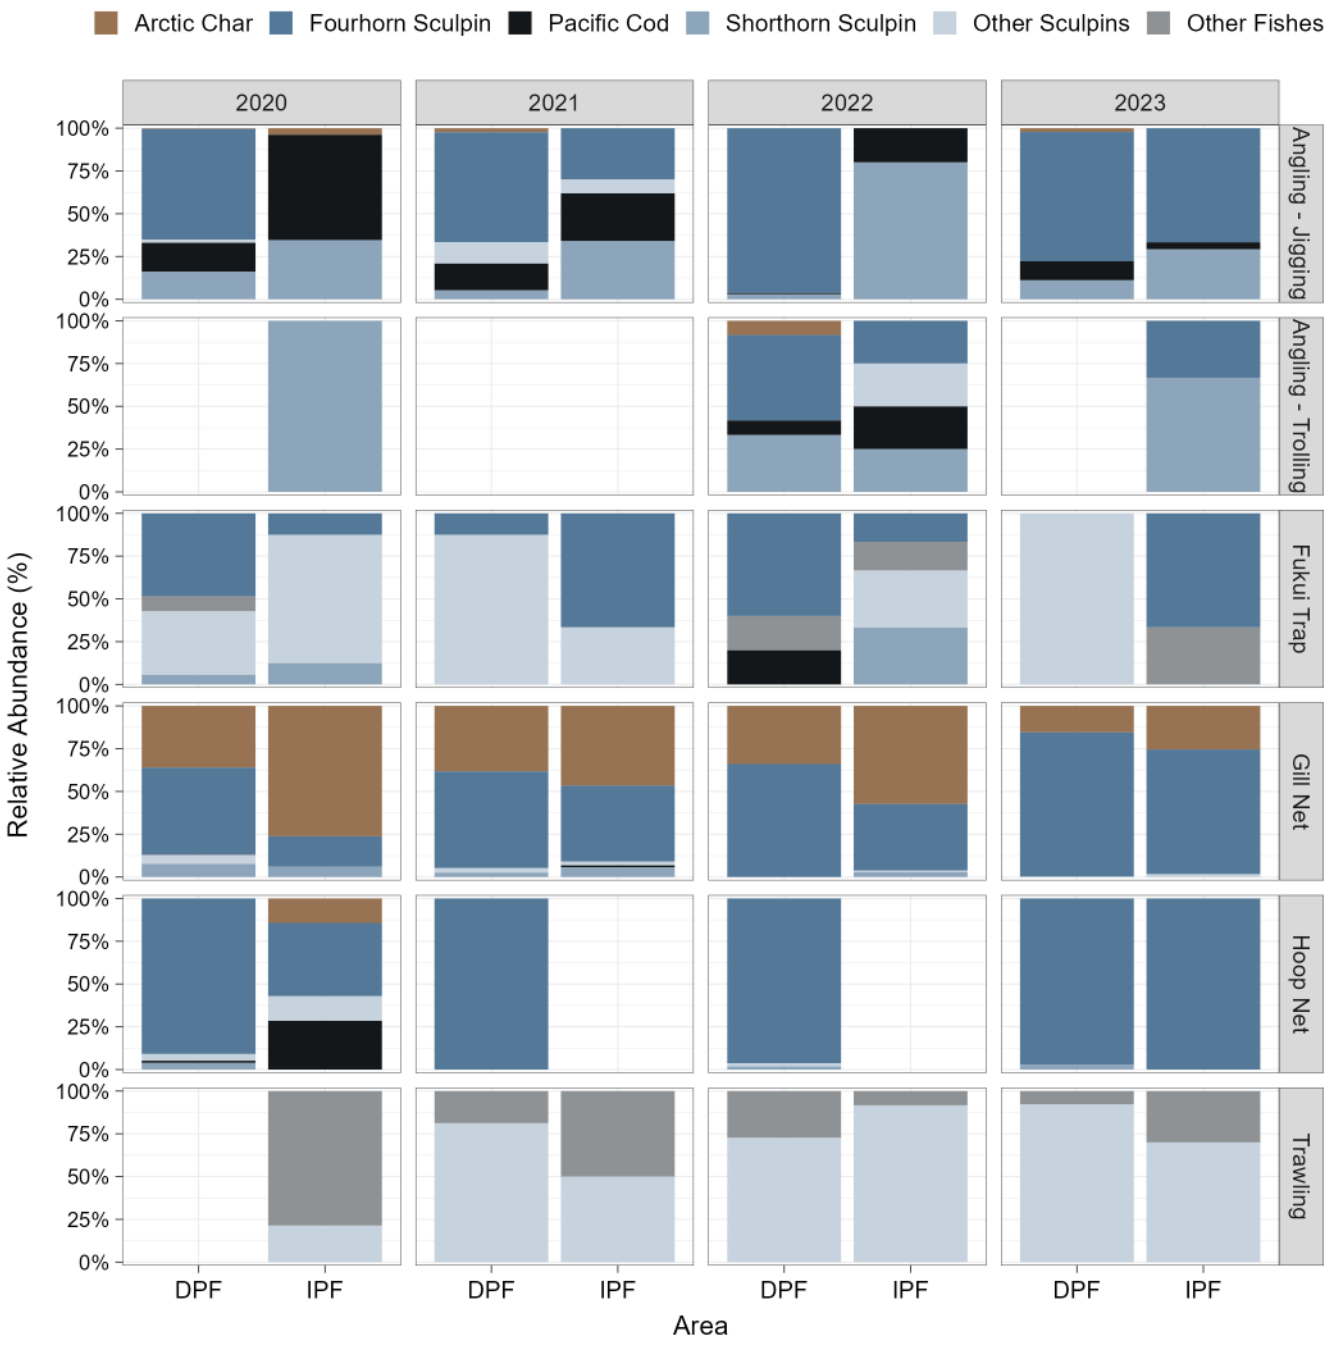

Figure 6-6: Relative Abundances of Grouped Taxa per Fishing Method and by Year (2020-2023) and Fishing Area (Direct Project Footprint [DPF] and Indirect Project Footprint [IPF])

Note: Pacific Cod (*G. macrocephalus*) is the new taxonomically accepted name of Greenland Cod (*G. ogac*). Fish taxa were grouped based on relative abundance percentages from 2020 to 2023 catch data. Taxa with abundances <5% were grouped as follows: other sculpins (Arctic Sculpin, Arctic Staghorn Sculpin, Ribbed Sculpin, Spatulate Sculpin, and unidentified sculpins) and other fishes (Arctic Alligatorfish, Arctic Cod, Atlantic Poacher, Atlantic Spiny Lumpsucker, Fourline Snakeblenny, Halfbarred Pout, Northern Sand Lance, Polar Cod, Saddled Eelpout, unidentified cods, and unidentified snailfish). Seine nets were excluded due to only one year of data (2020) collected.

6.5.2.2 Catch by Fishing Method

Trawling was a major driver in differences in taxa richness between 2020 and 2023; trawling taxa richness increased from three taxa in 2020 to seven taxa in 2021 with an increased number of trawling efforts resulting in catches of previously unrecorded fish in Milne Port (e.g., Atlantic Alligatorfish, Atlantic Poacher, Ribbed Sculpin, Spatulate Sculpin, and unidentified snailfish; Table 6-9; Appendix 6B). Trawling taxa richness decreased to four taxa in 2022, possibly due to fewer trawling efforts and increased efforts to prevent the trawl touching the seabed during deployment in 2022 (Table 6-9); however, taxa richness increased for trawling in 2023, possibly due to more trawling efforts than 2022 while maintaining efforts to prevent the trawl touching the seabed during deployment. While this shallower operation of the net may have allowed some demersal fishes to evade capture, the practice avoided potential environmental impacts of contact between the trawl and the seabed (e.g., disturbance of seabed and benthic biota).

Overall, taxa richness was higher in 2023 compared to all previous years but was only increased by one taxon compared to 2021 and 2022, suggesting that taxa richness had remained effectively stable over the years 2021 through 2023 (Table 6-9; Appendix D – Table 3). There were no strong trends in taxa richness by gear type over time. Taxa richness was one to two taxa lower in 2022 and 2023 relative to 2020 and 2021 for gill nets and jigging but showed no clear trend for other methods. Annual changes in taxa richness may be due to adjustments of sampling effort to achieve a balanced sampling of the two gear types and of two Fishing Areas, increased time devoted to exploratory fishing for a reference site in 2023, and/or interannual variation in catch.

Table 6-9: Taxa Richness by Fishing Method (2020-2023)

Fishing Method	Number of Taxa			
	2020	2021	2022	2023
Angling - Jigging	5	5	3	4
Angling - Trolling	1	0	5	2
Fukui Trap	5	2	6	3
Gill Net	6	5	4	4
Hoop Net	5	1	3	2
Long Line	-	0	-	-
Seine Net	3	-	-	-
Trawling	2	7	4	6
Total	9	11	11	12

Note: Only unique taxa are included – unidentified cods and sculpin were removed as they may be of an identified taxon. Longlining was excluded in 2022 as no fish were caught in 2021. Trolling did not catch fish in 2021. Seine nets were not deployed after 2020.

All Species Catch-Per-Unit-Effort

Mean CPUE of fishing methods was highly variable among fishing areas and years (Table 6-10; Appendix 6D – Figure 6). Mean CPUE of most fishing methods tended to be higher in the DPF compared to the IPF for all years, with the exception of trolling in 2020 and 2023, Fukui traps in all years, gill nets in 2020, and trawling in 2023 (Table 6-10).

Table 6-10: Catch Per Unit Effort Summary Statistics by Fishing Area (Direct Project Footprint [DPF], Indirect Project Footprint [IPF]) Fishing Method and Year, All Fish Species Combined

Method (CPUE Unit)	Year	Area	Sampling Events	CPUE Summary Statistic				
				Mean	Median	SD	Min	Max

		IPF	2	23.60	23.60	27.72	4.00	43.20

Overall, CPUE for angling by jigging differed significantly among sampling areas (p=0.012) but did not differ among sampling years (p=0.063) and there was no significant interaction (p=0.529; Table 6-11). Angling by jigging CPUE was higher in the DPF than in the IPF sampling area (effect size = 105%). Mean CPUE in both the DPF and IPF in 2023 was lower than in previous years, although observed differences were not significant (Figure 6-7A; Table 6-10).

In contrast to jigging, CPUE for angling by trolling differed among sampling years (p<0.001) but did not differ among sampling areas (p=0.470; Table 6-11). Interannual differences reflected natural variability with no obvious trends over time. Mean CPUE pooled among sampling areas was highest in 2022 (3.09±4.32 fish*hr^{-1}*rod^{-1}), differing from 2020 (p=0.031, effect size = -93%) and from 2023 (p=0.007, effect size = 637%). Pooled mean CPUE in 2020 was similar to 2023 (p=0.841; effect size = -48%).

Mean CPUE of Fukui traps remained low in 2023 for both fishing areas (≤0.01 fish*hr*trap^{-1}), consistent with mean values from previous years (Figure 6-7D). CPUE did not differ among sampling areas (p=0.336) or sampling years (p=0.079), and there was no significant interaction (p=0.429; Table 6-11).

As observed with angling by jigging, gill net CPUE differed significantly among sampling areas (p=0.003) but did not differ among years (p=0.161), with no significant interaction (p=0.324; Table 6-11). Pooled across sampling years, gill net CPUE was 78% higher in the DPF than in the IPF sampling area. Mean gill net CPUE in the DPF varied among years, whereas mean CPUE in the IPF showed little variation (Figure 6-7E; Table 6-10).

Mean CPUE values of hoop net fishing were consistently below 0.2 fish/hr among all sampling areas and years (Table 6-10; Figure 6-7). As with gill net and angling by jigging methods, CPUE of hoop nets differed significantly among sampling areas (p<0.001) but did not differ among sampling years (p=0.101; Table 6-11). Hoop net CPUE was 1,578% higher in the DPF compared to the IPF across sampling years.

Statistical power was low to detect up to 40% reduction in CPUE in the DPF relative to the IPF in 2023 for analyses where an interaction between year and area was included (angling-jigging, Fukui traps, and gill nets; Appendix 6E). The power to detect a 40% reduction in CPUE in 2023 relative to 2022 was also low for analyses that did not include an interaction in the model structure (angling-trolling and hoop nets). The significant effect of year found for hoop nets (Table 6-11) was due to the observed effect sizes, ranging from -93% to +637%, being considerably larger than the effect sizes assessed in the power analysis.

Trends in trawling CPUE were not evaluated statistically due to low sample sizes (Table 6-10). Trawling exhibited considerable variability in mean CPUE across different years and efforts (Table 6-10). In the DPF, mean CPUE ranged from 16.1 fish/hr in 2023 to 116.0 fish/hr in 2021 (Table 6-10). In the IPF, mean CPUE ranged from 4.76 fish/hr in 2021 to 333.00 fish/hr in 2020. Recently, in 2022 and 2023, CPUE by trawling appeared similar between sampling areas. Observed variability in CPUE of trawling may be attributed to interannual differences in trawling methods among sampling years, including trawling depths and efforts to avoid seabed contact during trawl deployment. The highest CPUE values were generally associated with interceptions of schools of juvenile fishes.

Table 6-11: Statistical Significance (*P*-Values) from Analysis of Catch Per Unit Effort relative to Year and Fishing Area, for each Fishing Method (2020-2023), All Fish Species Combined

Statistical Test	Angling – Jigging	Angling – Trolling	Fukui Trap	Gill Net	Hoop Net
Area	**0.012**	0.470	0.336	**0.003**	**<0.001**
Year	0.063	**<0.001**	0.079	0.161	0.101
Interaction	0.529	-	0.429	0.324	-

Note: Cells highlighted in blue and **bolded** indicate significance levels <0.05. '-' indicates not included in model. Long line, seine net, and trawling were excluded from this comparative analysis as longlines were not used in 2020, seine netting was not conducted in 2021 or 2022, and trawling in 2020 was limited to a single test of methods effort. Full analysis results are presented in Appendix 6D – Table 5.

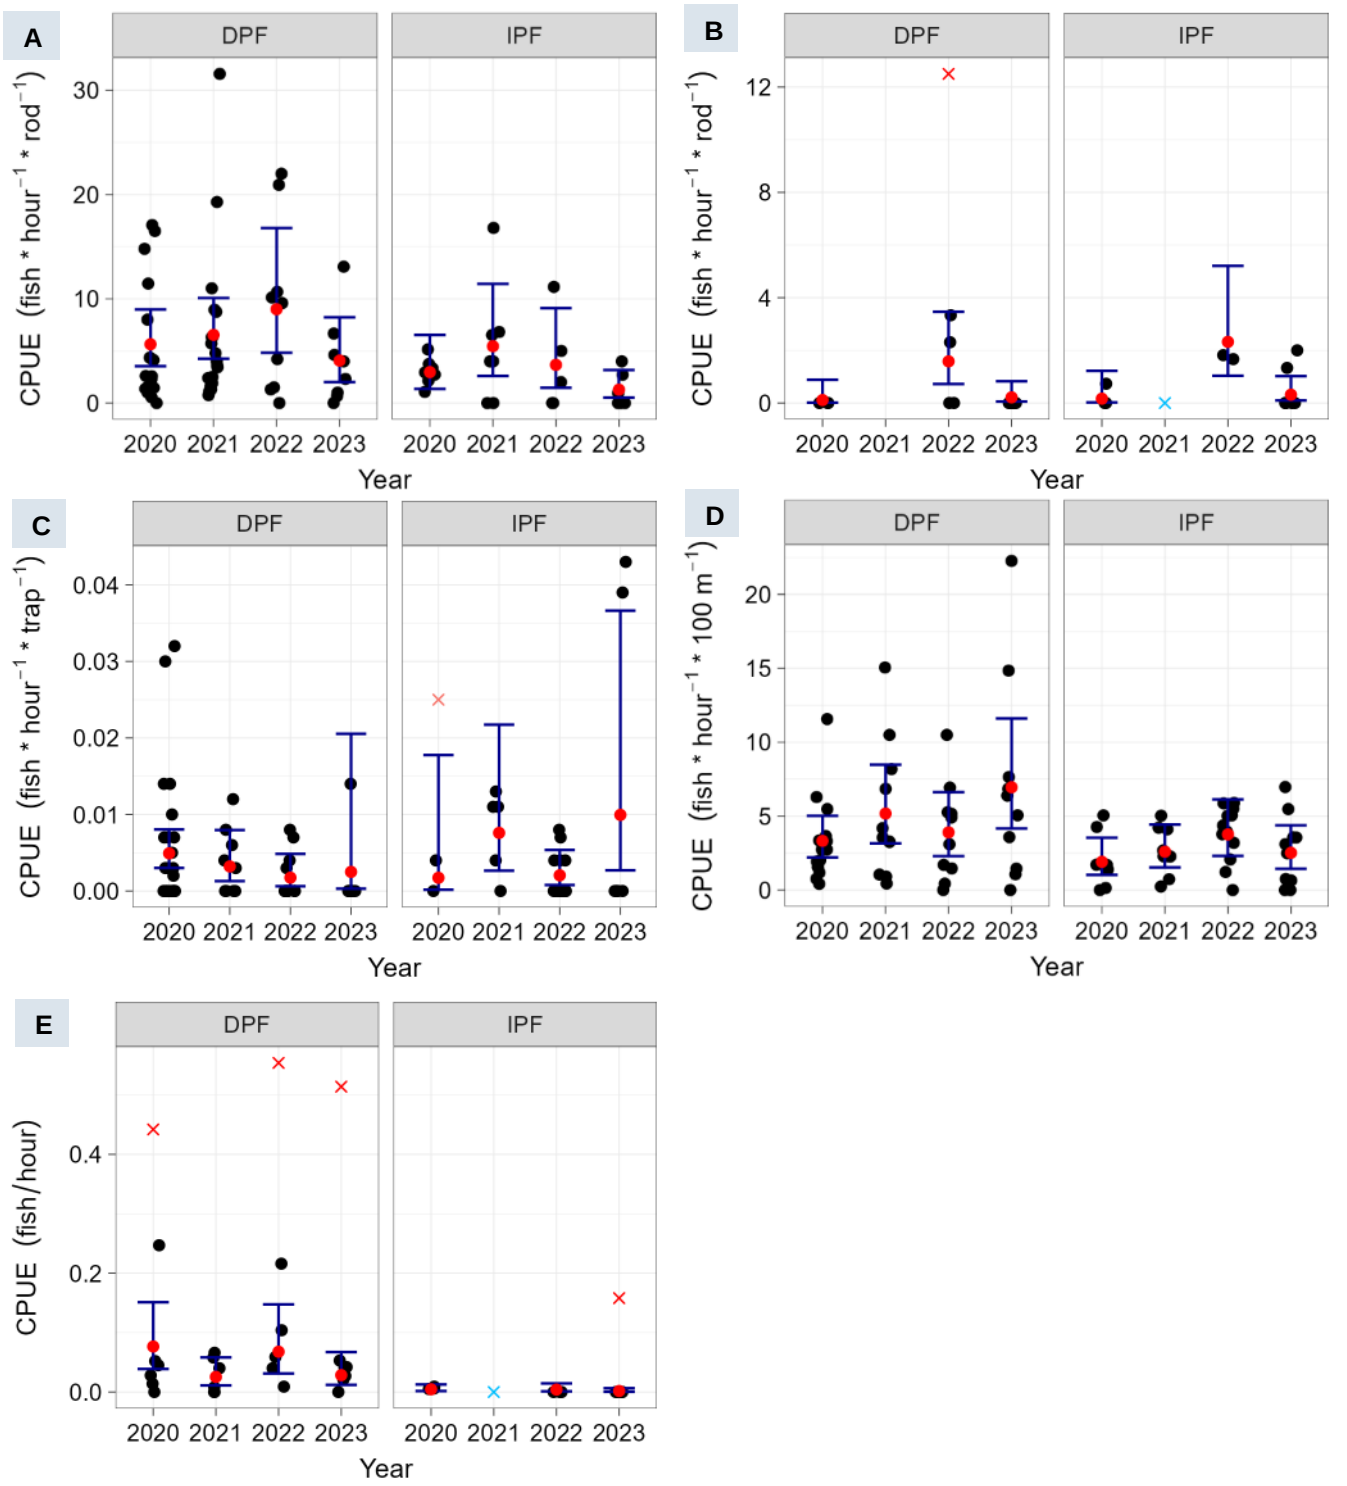

Figure 6-7: Observed (black points) and modeled estimates (red points and blue error bars) for CPUE of All Fish Species Combined (2020-2023) for A) Angling-Jigging; B) Angling-Trolling; C) Fukui Traps; D) Gill Nets; and E) Hoop Nets. Error bars are 95% confidence intervals.

Note: Red crosses = outliers/influential points. Blue crosses = data excluded from analysis.

Grouped Taxa Catch Per Unit Effort

Parallel trends were observed in the average CPUEs of taxonomic groups (specifically, groups with <5% relative abundance in totalled catches from 2020 to 2023 were consolidated). This trend aligned with the variations observed in the relative abundance of catch counts across different fishing methods and areas (Table 6-12; Figure 6-8).

Table 6-12: Grouped Taxa Mean Catch Per Unit Effort by Fishing Method and Fishing Area (2020-2023)

c	Year	Area	Arctic Char	Fourhorn Sculpin	Pacific Cod	Shorthorn Sculpin	Other sculpins	Other fishes

Note: Fish taxa were grouped based on relative abundance percentages from 2020 to 2023 catch data. Taxa with abundances <5% were grouped as follows: other sculpins (Arctic, Arctic Staghorn, Ribbed, Spatulate, and unidentified sculpins) and other fishes (Arctic Alligatorfish, Arctic Cod, Atlantic Poacher, Atlantic Spiny Lumpsucker, Fourline Snakeblenny, Halfbarred Pout, Northern Sand Lance, Polar Cod, Saddled Eelpout, unidentified cods, and unidentified snailfish). Pacific Cod (*G. macrocephalus*) is the new taxonomically accepted name of Greenland Cod (*G. ogac*).

Mean CPUE for angling by jigging in 2023 was similar to that of previous years' (Figure 6-8). Fourhorn Sculpin were the dominant fish caught by jigging in the DPF in all sampling years, with mean CPUE values ranging from 2.61 to 8.31 fish*hr^{-1}*rod^{-1} (Table 6-12). In the IPF, fish species abundance varied by year: in 2020 and 2022, Shorthorn Sculpin were dominant (2020: 1.61 fish*hr^{-1}*rod^{-1}; 2022: 2.83 fish*hr^{-1}*rod^{-1}), whereas in 2021, Pacific Cod were dominant (2.46 fish*hr^{-1}*rod^{-1}), and in 2023, Fourhorn Sculpin were dominant (0.71 fish*hr^{-1}*rod^{-1}; Table 6-12).

When evaluated by taxon grouping, mean CPUE for angling by jigging varied by group (Table 6-12). For Fourhorn Sculpin, CPUE varied significantly among both sampling areas and years (p=0.004, respectively; Table 6-13)[3]. Mean Fourhorn Sculpin CPUE in the DPF was 597% higher than in the IPF (p=0.002; Table 6-13). Mean CPUE in 2020 was significantly lower than in all subsequent years across both sampling areas, with mean CPUE differing from 94% to 96% lower when compared to 2023 and 2022, respectively (p=0.003; Table 6-13; Figure 6-9A). Mean CPUE for Pacific Cod and Shorthorn Sculpin captured by jigging varied among sampling areas and years but was not evaluated statistically due to low total catch numbers. Mean CPUE for Pacific Cod was generally higher in the DPF compared to the IPF, with the exception of 2023 (Table 6-12). In contrast, mean CPUE for Shorthorn Sculpin was generally lower in the DPF compared to the IPF, with the exception of 2020 and 2023 (Table 6-12). Mean

[3] In the analysis of Fourhorn Sculpin CPUE, the model for angling-jigging did not include the interaction between area and year due to lack of model convergence.

CPUE values for other taxon groupings captured by jigging were generally low (<1 fish*hr^{-1}*rod^{-1}) for in 2020 and 2021, with none of these fishes captured in 2022 and 2023 (Table 6-12; Figure 6-8).

Mean CPUE values for angling by trolling were generally low (i.e., <0.5 fish*hr^{-1}*rod^{-1}) for all taxon groupings across each sampling area and year, with the exception of Fourhorn Sculpin captured in the DPF in 2022 (mean CPUE: 2.63 fish*hr^{-1}*rod^{-1}; Table 6-12; Figure 6-8). Variation in the CPUE of Fourhorn Sculpin captured by trolling could not be analyzed due to a high frequency of zeroes in the data.

Fukui traps generally had a low success of capturing fish: mean CPUE values were consistently low for all taxon groupings across all sampling areas and years (i.e., <0.01 fish*hr^{-1}*trap^{-1}; Table 6-12; Figure 6-8). As with trolling, CPUE for Fourhorn Sculpin could not be analyzed due to a high frequency of zeroes in the data.

Mean CPUE of gill nets in 2023 was greatest for Fourhorn Sculpin (DPF: 5.66 fish*hr^{-1}*100m^{-1}; IPF: 0.76 fish*hr^{-1}*100m^{-1}) followed by Arctic Char (DPF: 1.23 fish*hr^{-1}*100m^{-1}; IPF: 0.76 fish*hr^{-1}*100m^{-1}; Table 6-12; Figure 6-8). Mean CPUE for Fourhorn Sculpin was consistently higher in the DPF compared to the IPF between 2020 and 2023, with the highest CPUE occurring in 2020 in the IPF and the lowest CPUE in 2023 in the IPF (Table 6-12; Figure 6-8). Arctic Char CPUE varied between sampling areas across years: in the IPF, the highest CPUE occurred in 2023 while the lowest CPUE occurred in 2021 (Table 6-12; Figure 6-8). Mean CPUE values for other taxon groupings captured using gill nets were low (i.e., <0.5 fish*hr^{-1}*100m^{-1}) in all sampling areas across years (Table 6-12; Figure 6-8).

Differences in gill net CPUE for Fourhorn Sculpin and Arctic Char were analyzed statistically (Table 6-13); differences in CPUE for other taxon groupings could not be analyzed due to the high frequency of zeroes in the data. For Fourhorn Sculpin captured using gill nets, CPUE varied significantly among sampling areas and across years (p=<0.001, p=0.008, respectively; Table 6-13). Mean CPUE in the DPF was 219% higher than in the IPF (p=<0.001; Table 6-13) across years. Mean CPUE in 2020 in both sampling area combined was 76% lower than in 2023 (p=0.002; Table 6-13; Figure 6-9B). Statistical power was low to detect up to 40% reduction between 2022 and 2023 for Fourhorn Sculpin (Appendix 6E); the original analysis was able to detect significant effects due to considerably larger observed effect sizes. For Arctic Char, the interaction between year and area was significant (p=0.011; Table 6-13), indicating differences in trends of CPUE between the two areas over time. Pairwise comparisons between sampling areas by year indicated that CPUE differed significantly between sampling areas in 2023 (p=0.006; effect size = 415%) but did not differ in other years. Within the DPF, no significant pairwise differences were observed among years; in contrast, within the IPF, mean CPUE in 2023 was significantly lower than previous years (2020: p=0.012, effect size = 531%; 2021: p=0.024, effect size = 427%; 2022: p=0.001, effect size = 721%; Table 6-13; Figure 6-9C). Statistical power was low to detect up to 40% reduction between the IPF and DPF in 2023 for Arctic Char (Appendix 6E) due to data variability, low CPUE in the IPF, and lack of differences between areas in preceding years. The significant interaction for Arctic Char gill net data and the significant effects of year for Fourhorn Sculpin jigging and gill net data (Table 6-13) was due to the observed effect sizes, ranging from +73% to +597%, being considerably larger than the effect sizes assessed in the power analysis.

Mean CPUE using hoop nets in 2023 was similar to mean values in previous years (Table 6-12). Overall, mean CPUE was greater in the DPF compared with the IPF; Fourhorn Sculpin were most frequently caught by hoop nets, compared with other taxon groupings (Table 6-12; Figure 6-8). For other taxon groups, mean CPUE values were low (i.e., <0.1 fish/hr) among sampling areas and years (Table 6-12; Figure 6-8).

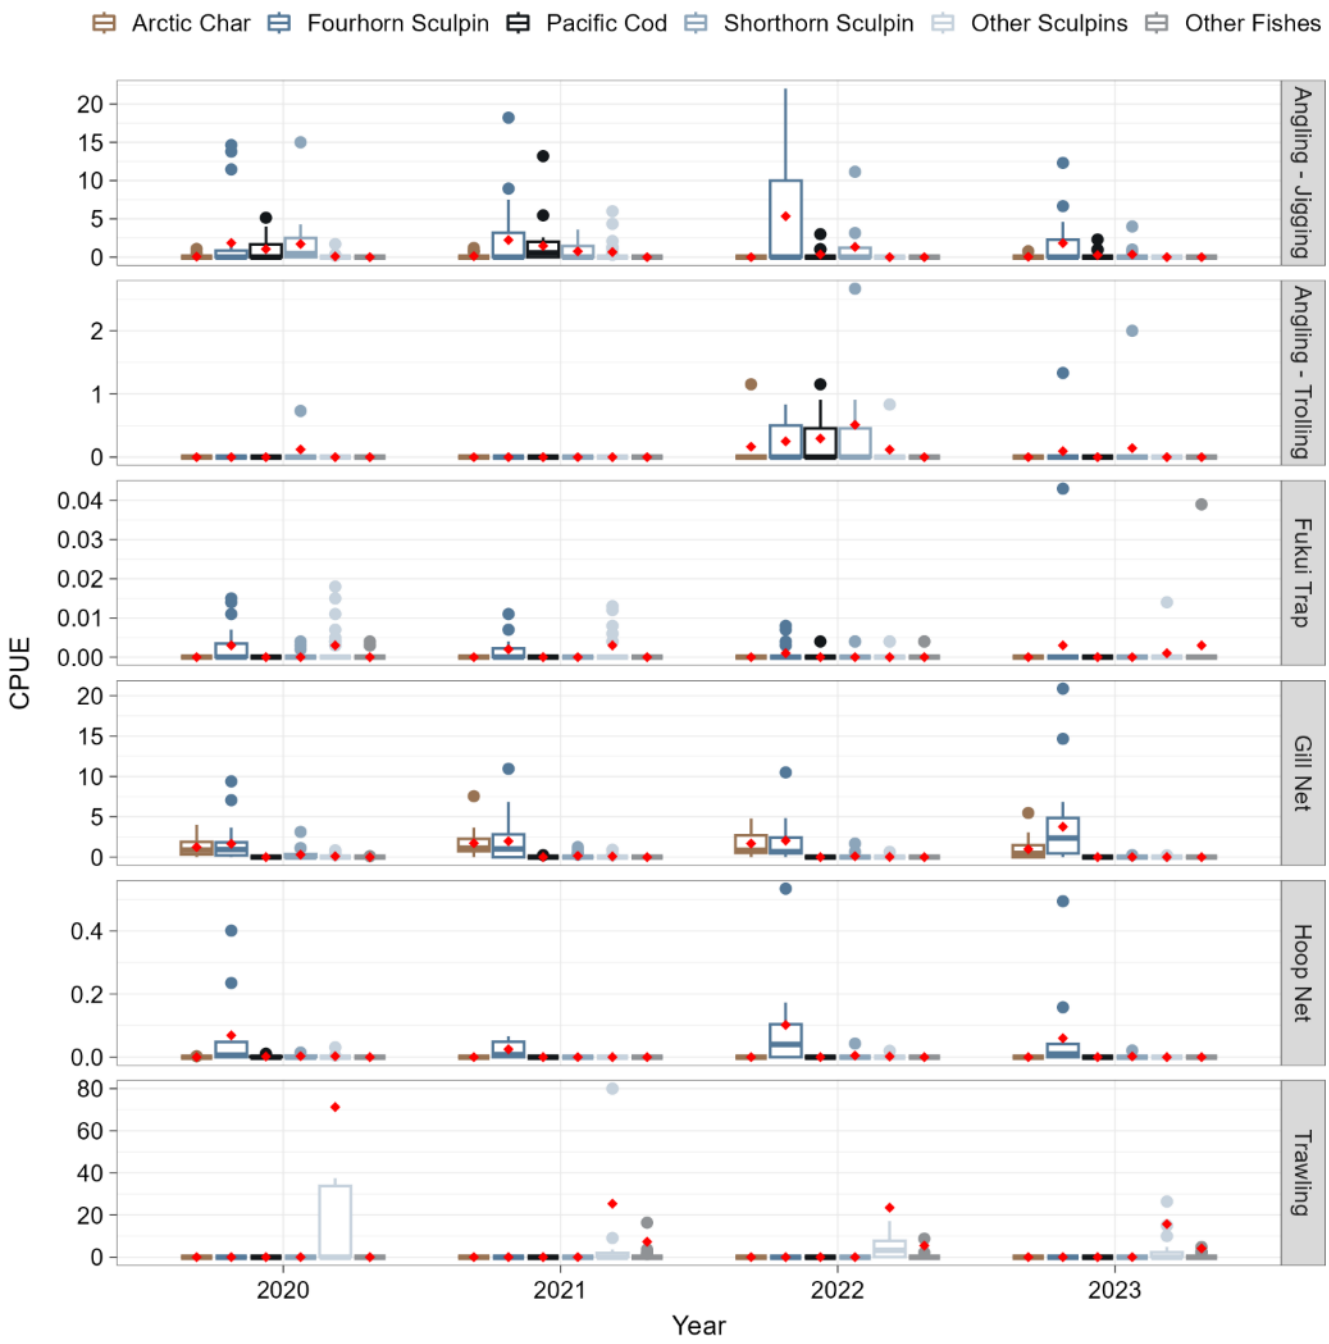

Figure 6-8: Grouped Taxa Mean Catch Per Unit Effort by Fishing Method (2020-2023)

Note: Pacific Cod (*G. macrocephalus*) is the new taxonomically accepted name of Greenland Cod (*G. ogac*). Red diamonds indicate mean values. Fish taxa were grouped based on relative abundance percentages from 2020 to 2023 catch data. Taxa with abundances <5% were grouped as follows: other sculpin (Arctic Sculpin, Arctic Staghorn Sculpin, Ribbed Sculpin, Spatulate Sculpin, and unidentified sculpin) and other fish (Arctic Alligatorfish, Arctic Cod, Atlantic Poacher, Atlantic Spiny Lumpsucker, Fourline Snakeblenny, Halfbarred Pout, Northern Sand Lance. Polar Cod, Saddled Eelpout, unidentified cod, and unidentified snailfish). Seine nets were excluded from the figure as there was only one year of data, which is presented in Table 6-12. Longlining was also excluded from the figure as no fish were caught in the single year of sampling, 2021, which resulted in discontinuation of the program in 2022. High outlier values were removed from jigging in 2021 DPF, gill net 2020 IPF, and trawling 2020 IPF for better visualization. See Table 6-10 for excluded values.

Fish catches when trawling often comprised rarely observed taxon groups, with taxa frequently captured using other fishing methods rarely being captured using this method. In the IPF, the highest CPUE value occurred in 2020 (262.50 fish/hr), for the 'other fish' grouping (i.e., Arctic Alligatorfish, Arctic Cod, Atlantic Spiny Lumpsucker, Atlantic Poacher, Fourline Snakeblenny, Halfbarred Pout, Northern Sand Lance, Polar Cod, Saddled Eelpout, unidentified cods, and unidentified snailfish). CPUE in 2021 was also relatively high, with 94.55 fish/hr for 'other sculpin' (i.e., Arctic, Arctic Staghorn, Ribbed, Spatulate, and unidentified sculpins; Table 6-12). Mean CPUE values for all taxon groupings in 2023 were slightly lower than those in 2022 (Table 6-12). 'Other fish' showed larger ranges between areas than 'other sculpin' between 2022 and 2023, but trends were variable between years in terms of which area had higher CPUE. The mean CPUE for both sampling areas decreased from 2022 to 2023 for 'other sculpin' (23.49 fish/hr and 15.70 fish/hr, respectively), but was similar for 'other fish' (5.46 fish/hr and 4.13 fish/hr, respectively; Table 6-12); Figure 6-8).

Table 6-13: Statistical P-Value Results from ANOVA of Catch Per Unit Effort for Arctic Char and Fourhorn Sculpin by Fishing Method, Year, and Fishing Area (2020-2023)

Statistical Test	Angling – Jigging	Angling – Trolling	Fukui Trap	Gill Net	Hoop Net
Arctic Char					
Area	Not analyzed	Not analyzed	Not analyzed	0.427	Not analyzed
Year				**0.045**	
Interaction				**0.011**	
Fourhorn Sculpin					
Area	**0.004**	Not analyzed	Not analyzed	**<0.001**	Not analyzed
Year	**0.004**			**0.008**	
Interaction	No interaction included in model			0.697	

Note: Cells highlighted in blue and bolded indicate significance levels <0.05. Longlining, seine net, and trawling were excluded from this comparative analysis as longlines were not used in 2020 or 2022, seine netting was not conducted in 2021 or 2022, and trawling in 2020 was limited to a single proof of concept effort. Full analytical results are presented in Appendix 6D – Tables 6 and 7.

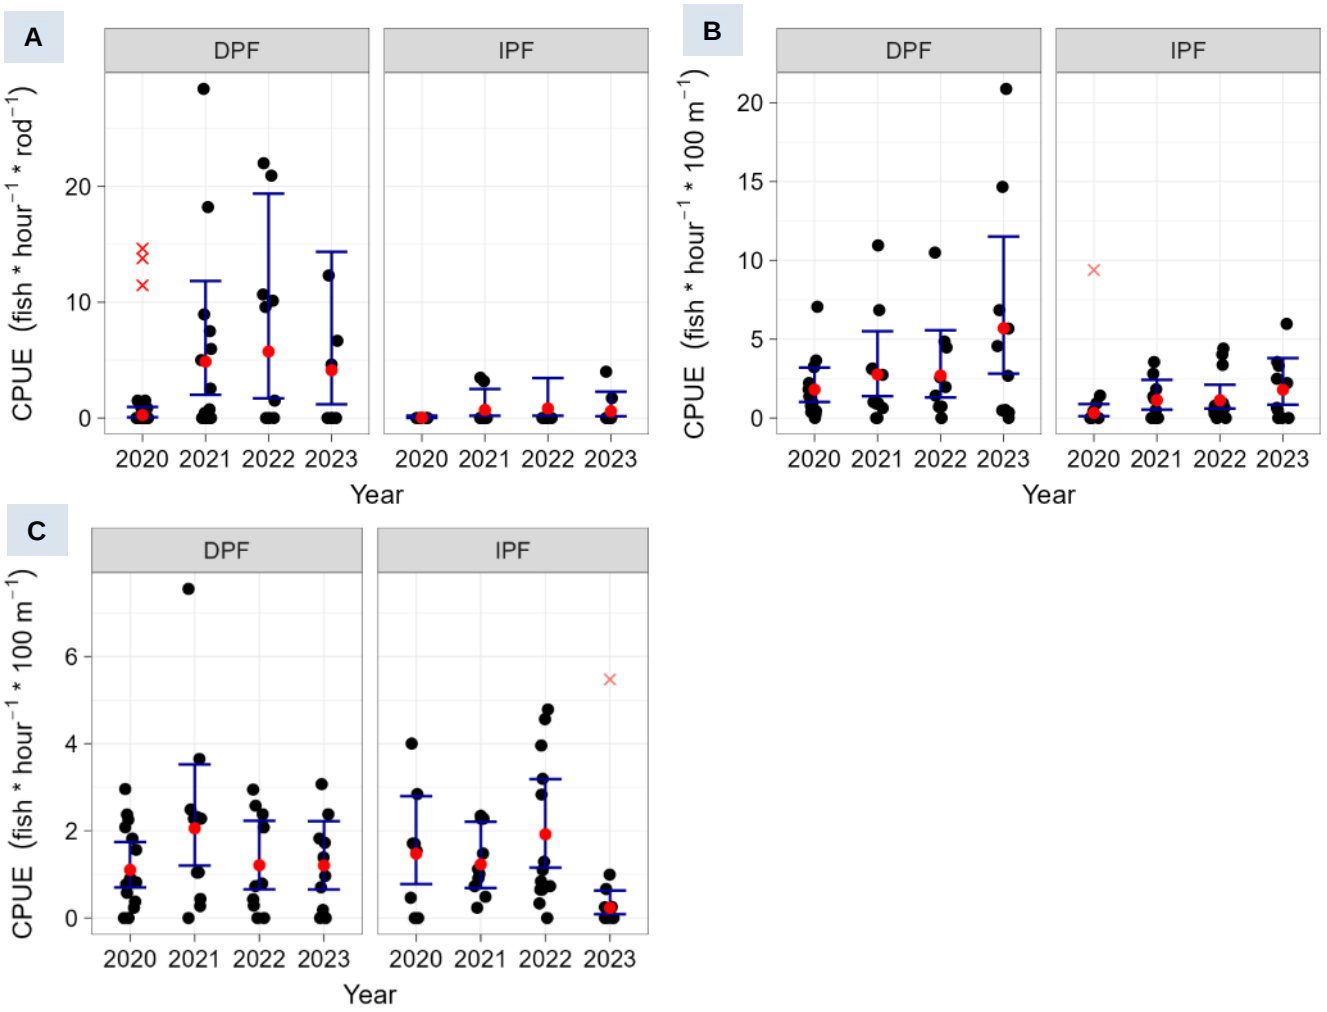

Figure 6-9: Observed (black points) and modeled estimates (red points and blue error bars) for CPUE (2020-2023) of A) Fourhorn Sculpin for Angling-Jigging; B) Fourhorn Sculpin for Gill Nets; and C) Arctic Char for Gill Nets. Error bars are 95% confidence intervals.

Note: Red crosses = outliers/influential points.

6.6 Discussion

In total, 422 individual fish, representing 12 known taxa were recorded in the DPF and IPF from 82 fishing efforts using several gear types during the 2023 open water survey season in Milne Port. Species richness in 2023 was the highest in the 2020-2023 time series, although total catch was the lowest. No new records of fish taxa were reported in Milne Inlet in 2023. An Atlantic Spiny Lumpsucker was captured for the first time during fishing efforts, however, this species was observed in Milne Port previously during the freight dock offsetting habitat surveys in 2021 (Golder 2022).

It is likely that the spatial redistribution of fishing effort within the study area contributed to the lower catch numbers. In order to identify a suitable reference area for the MEEMP fish health sampling program (see Chapter 7.0 Fish Health and Tissue Chemistry), the fish team spent more time sampling outside of Milne Port and there were fewer days of Milne Port fish sampling in 2023 than in 2022. Within Milne Port, more time than usual was spent fishing the western shore near Phillips Creek, where previously very few efforts were located. This was intended to further characterize the marine fish community in Milne Port, but few fish were captured during efforts on the western shore.

Statistical analyses of CPUE evaluated separately for each fishing method, which provided a more valid approach to compare changes in catch rate rather than considering catch numbers unadjusted for effort, indicated there was no reduction of the fish community by activity at the Port. Analyses of total CPUE (all fish species combined) indicated higher CPUE in the DPF compared to the IPF for angling-jigging, gill net, and hoop net catches and no effect of fishing area for angling-trolling and Fukui trap catches. For Arctic Char, there was no significant difference in CPUE between the DPF and IPF for gill netting, the only fishing method that could be analyzed. For Fourhorn Sculpin, analysis was conducted for two fishing methods (angling-jigging and gill net, the major methods by which Fourhorn Sculpin was captured) and both indicated CPUE was higher in the DPF compared to the IPF. This may relate to the use of constructed rocky reef habitat around the ore and freight docks by Fourhorn Sculpin.

Annual comparisons of CPUE for all fish species combined, by fishing method, were significantly different only for angling-trolling, for which the 2023 catch rates were lower than those in 2022. There was a significant effect of year and a significant interaction of year and FA for Arctic Char; similar CPUEs were observed in the IPF vs. DPF in years 2020 through 2022, but in 2023 the mean CPUE in the DPF (CPUE of 1.23) was almost double that in the IPF (CPUE of 0.76), as was also the case in 2021. In 2020 and 2022, the CPUE of Arctic Char was higher in the IPF. The CPUE of Arctic Char has been highly variable over time, particularly in the IPF. While the CPUE of Arctic Char in the DPF in 2023 was comparable to observed CPUEs in 2020 through 2022, the CPUE in the IPF was the lowest in the 2020-2023 time series. For Fourhorn Sculpin, angling-jigging and gill net CPUEs were both significantly higher in the DPF than in the IPF, continuing the trend seen from 2020 to 2023.

Overall, the results support the interpretation that existing mitigation measures were functioning as intended and that current Project activities were not resulting in adverse effects on the local marine fish communities in Milne Port.

Modifications to the monitoring program for the fish community over the past several years have focused on improving the statistical power of the monitoring. One approach to do so would be the elimination of sampling methods that yield relatively lower catches of fish, so as to focus on increasing the number of efforts conducted for more effective fishing methods. To that end, a comparison of hoop net versus Fukui trap catches was conducted from 2020-2022, and for an additional year in 2023 with closer matching of fishing effort and deployment location of the two methods.

Over the four-year trial study period, hoop net efforts yielded over twice as many captured fish (n=191) compared to Fukui traps (n=75), despite hoop nets having half the number of total efforts and half the number of total hours fished than the Fukui traps, totalled over all years. In 2023, when Fukui trap and hoop net efforts were standardized to match the location of deployments and the total number of set hours, hoop nets captured ten times the number of fish compared to Fukui traps with an average CPUE six times greater than that of Fukui traps. Fukui trap efforts in 2023 caught only four individuals from three taxa (Arctic Sculpin, Fourhorn Sculpin, and Polar Cod), with no significant differences in Fukui trap efficiency over time (<0.05 fish*hr^{-1}*trap^{-1}). As a result of the four-year comparison, it is recommended that the use of Fukui traps be discontinued in 2024, and efforts be increased for hoop net fishing.

The effectiveness of angling-trolling versus angling-jigging was also reviewed to determine if one of these methods could also be discontinued. Over the years 2020 to 2023 and between the two FA, the CPUE of angling-trolling ranged from zero to 3.63 fish*hr^{-1}*rod^{-1} (with three occurrences of zero catch rates) whereas CPUE of angling-jigging ranged from 0.96 to 8.92 fish*hr^{-1}*rod^{-1}. High occurrences of zero catch rates limits the ability to statistically analyse the angling-trolling data (e.g., Table 6-13). Taxa captured by angling-trolling are commonly caught via other fishing methods during open-water surveys. It is therefore recommended that the use of angling-trolling be discontinued in 2024a, and efforts be increased for angling-jigging.

It is possible that increasing sampling effort for angling-jigging and hoop nets would increase statistical power, but there remains a possibility the resulting statistical power might still not be sufficient. If that were to occur, it is advisable to focus interpretation on effect sizes (rather than statistical significance) which can provide a route to interpret trends even in cases where statistical power is not sufficient to capture changes in fish CPUE.

Overall, fishing methods were deemed effective in characterizing the marine fish community in terms of species presence and relative abundance. Fish sampling from 2020 to 2023 generally yielded comparable representation of the dominant fish species in Milne Port (Arctic Char, Fourhorn Sculpin and Shorthorn Sculpin) relative to previous years. The delineation of FAs and the standardization of fishing methods established in 2021 should continue as they appear to be effective means of assessing interannual change in relative fish abundance and distribution at Milne Port.

6.7 Conclusions and Recommendations

This chapter addresses 2023 program objectives, including the characterization of species composition and relative abundance of fish at Milne Port. Total catch and diversity of fish species were generally comparable to 2020 to 2022 results. Importantly, higher fish catches have been recorded closer to Project infrastructure than further away, indicating that the Project has not adversely affected the local marine fish community. Monitoring data from 2023 aligned with FEIS predictions, and subsequent ERP (Early Revenue Phase) addendums, which predicted the potential for minor and localized effects on fish and fish habitat.

Recommendations for the 2024 MEEMP sampling program include maintaining standardized fishing efforts as was done from 2020 to 2023 and continuing to remain consistent in the level of effort between the FAs so significant changes in the Milne Port area fish community can be identified. Fishing gear efficiencies were also evaluated, with a recommendation to continue to utilize gill nets, angling-jigging, hoop nets, and trawls while discontinuing the use of Fukui traps and angling-trolling due to consistently low catch numbers over the past four years. With the removal of Fukui traps and angling-trolling from the program, it may be feasible to increase the number of efforts per area of the remaining fishing methods (i.e., angling-jigging, gill nets, hoop nets, and trawling) in 2024 to increase the statistical power to detect effect sizes of interest. However, because of high variability in the fish catch data, power may still not be sufficient to reliably identify significant differences; in this case, it may be advisable to assess differences between areas using effect sizes rather than a strict adherence to statistical significance.

6.8 Closure

We trust this information is sufficient for your needs at this time. Should you have any questions or concerns, please do not hesitate to contact Phil Rouget, on behalf of the undersigned, at +1 250 419 4945.

TITLE: Mary River Project

OBJECTIVES OF RESEARCH:
Baffinland Iron Mines Corporation (Baffinland) was issued Scientific Research Licence 02 030 22R-M (the Licence) on April 26, 2022, by the Nunavut Research Institute (NRI). The Licence, along with other permits and approvals, allowed Baffinland to conduct select monitoring programs for the Mary River Project in 2022 as prescribed by Project Certificate No. 005 – Amendment 4 and Type "A" Water Licence No. 2AM-MRY1325 – Amendment 1. Baffinland requests the renewal of this multi-year licence to continue monitoring programs in 2023.

TERMS & CONDITIONS:
The holder of the licence will be bound by the terms and conditions of the Nunavut Impact Review Board Screening Decision Report and the Department of Culture & Heritage archaeological sites terms and conditions. These terms and conditions will form part of this licence.

DATA COLLECTION IN NU:
DATES: February 7,2023 to December 31,2023
LOCATION: Steensby Port, Mary River, Milne Port/Road

Scientific Research License 02 012 23R-M expires on December 31,2023
Issued at Iqaluit, NU on February 24,2023

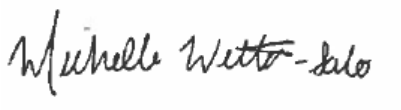
Subject: Animal Use Protocol - Letter of Approval

Dear Phil,

Your 2022 Animal Use Protocol (AUP) "Baffinland Iron Mines Corp, Mary River Project, 2022 Marine Environmental Effects Monitoring Program (MEEMP) and Marine Habitat Offset Monitoring Program." received a multiyear approval last year by the Ontario, Prairie and Arctic Animal Care Committee (OPA-ACC) and has now been assigned number OPA-ACC-2023-05 for this year.



Keep this signed letter of approval as well as the signed AUP application form for your records. Please be advised that should there be a need to revise the protocol you are requested to contact the OPA-ACC and obtain approval prior to proceeding.

The Canadian Council on Animal Care requires post approval monitoring of AUPs. The OPA-ACC will be randomly choosing AUPs and asking for photographs or video that shows the handling or interaction of animals for these projects.

In addition, you are required to submit a brief report annually within 30 days of completion of the project outlining the unexpected changes to the protocol, the number of animals used and any unanticipated results. If injuries or mortalities occur, an incident report must be provided.

Feel free to contact me if you have any questions or concerns.

Sincerely,

Michelle Wetton-Salo

Chairperson of OPA-ACC

Licence #: S-23/24-1027-NU

Philippe Rouget
3795 Carey Road 2nd floor
Victoria, BC, CA V8Z 6T8

Dear Philippe Rouget,

Enclosed is your amended Licence to Fish for Scientific Purposes issued pursuant to Section 52 of the Fishery (General) Regulations.

Failure to comply with any of the conditions specified on the attached licence may result in a contravention of the Fishery (General) Regulations.

Please be advised that this licence only permits those activities stated on your licence. Any other activity may require approval under the Fisheries Act or other legislation. It is the Project Authority's responsibility to obtain any other approvals.

Please ensure that you include the licence number and project title in any future correspondence and that you complete the Summary Harvest Report upon completion of activities under this licence.

Yours truly,

Colin Charles
Fisheries Management
Arctic Region
Fisheries and Oceans Canada

LICENCE TO FISH FOR SCIENTIFIC PURPOSES

S-23/24-1027-NU

Pursuant to Section 52 of the Fishery (General) Regulations, the Minister of Fisheries and Oceans hereby authorizes the individual(s) listed below to fish for scientific purposes, subject to the conditions specified.

Project Authority: Philippe Rouget — Golder Associates Ltd.
3795 Carey Road 2nd floor
Victoria, BC, CA V8Z 6T8

Other Personnel: Phil Rouget, Andrea Locke, Patricia Tomliens, Ronnie Komangapik, Niallan O'Brien, Daniel Vicente, Kristin Westman, Paul Hinton, Josephee Macpa, Stephanie Davis, Alison Loeppky, Marie-Claire Robitaille, Rob Hollingshead, Frikkie VanDerVy

Objectives: Baffinland Iron Mines Corp. - Mary River Project - 2023 Marine Environmental Effects Monitoring Program (MEEMP) and Marine Habitat Offset Monitoring Program, Baffin Island, Nunavut

The Project objectives are to conduct sampling to adhere to the terms and conditions of Baffinland to operate theexisting Mary River Mine and Port Facility in Milne Inlet (North Baffin Island) through the implementation of the2023 monitoring programs for the Marine Environment in accordance with the Project Certificate terms and
Conditions issued for the Mary River Project. The 2023 programs for the Marine Environment include the following program components:
- 2023 Marine Environmental Effects Monitoring Program (MEEMP)
- 2023 Non-Indigenous and Aquatic Invasive Species (NIS/AIS) Monitoring Program

CONDITIONS

Specified Conditions:

See Appendix A for map of authorized sampling areas

Other Species Encountered may include: Snakeblenny, Slender (Lumpenus fabricii); Cod, Polar (Arctogadus glacialis); Lumpsucker, Spiny (Eumicrotremus orbis); Lumpsucker, Atlantic Spiny (Eumicrotremus spinosus);

Sample Size for species listed above: 500 LIVE, 100 DEAD

All weights are listed in kilograms (kg)

Waters:

Water Body: Milne Inlet
Point A: 72° 20' N, 80° 30' W

Species: Benthos

Gear: Ponar dredge
Van Veen Grab

Total Weight	Weight Live	Weight Dead	Number Alive	Number Dead	Number Tows	Number Sets	Hours	Minutes
	200.00	100.00

Fishing Period: July 21, 2023 to September 01, 2023

A copy of this licence must be available at the study site and produced at the request of a fishery officer.

Live fish may not be retained unless specified in the conditions of this licence.

The licence holder shall immediately cease fishing when the total fish killed or live sampled reaches any of the maximums set for any of the species listed.

Transportation:

Other approvals/permits may be necessary to collect or transport certain species, such as Marine Mammal Transportation Permits. For marine mammal parts, products and derivatives a Marine Mammal Transportation Licence is required for domestic transport and, for international transport a Canadian CITES Export Permit is also required.

Report on Activities:

The Project Authority will submit to the License Delivery Officer, Department of Fisheries and Oceans, within one month of the expiry date, a report stating:

i) whether or not the field work was conducted; and if conducted

ii) waterbody location, fishing coordinates, gear types used at each coordinate, numbers or amount of fish (by species) collected and/or marked and the date or period of collection.

A Summary Harvest Report template is provided by the License Delivery Officer at time of issuance of this licence .

The Project Authority also will provide a copy of any published or public access documents which result from the project . Information supplied will be used for population management purposes by the Department of Fisheries and Oceans and becomes part of the public record.

All documents should be sent to:

[1] NFC = no fish caught

[2] AALG = Arctic Alligatorfish; ARCH = Arctic Char; ARSC = Arctic Sculpin; ASLP = Atlantic Spiny Lumpsucker; FHSC = Fourhorn Sculpin; GRCD = Greenland Cod; POCD = Polar Cod; RBSC = Ribbed Sculpin; SAEP = Saddled Eelpout; SHSC = Shorthorn Sculpin; SPSC = Spatulate Sculpin;STSC = Arctic Staghorn Sculpin; UNCD = Unknown Cod

[3] M = Male; F = Female; U = Unknown

[4] A = Adult; J = Juvenile; F = Fry; U = Uknown

[5] DPF = Direct Project Footprint; IPF = Indirect Project Footprint; REF-K = Chapter 7.0 fish health reference exploration in Koluktoo Bay

APPENDIX C

Photographs

Photo 1: Angling – jigging effort ANJ01 below the West Ore Dock in the DPF (Direct Project Footprint).

Photo 2: Angling – trolling effort ANT11 off East Beach in the DPF.

Photo 3: Gill net effort GN11 deployed off East Beach in the DPF.

Photo 4: Hoop net effort HN14 deployed on the southwest side of Milne Port in the IPF (Indirect Project Footprint).

Photo 5: Trawling effort TR01 being deployed mid-bay in front of the Ore Dock in the DPF.

Photo 6: Fourhorn Sculpin (*Myoxocephalus quadricornis*) captured in hoop net effort HN07 in the DPF.

Photo 7: Arctic Char (*Salvelinus alpinus*) captured in gill net effort GN11 in the IPF.

Photo 8: Shorthorn Sculpin (*Myoxocephalus scorpius*) captured in angling-trolling effort ANT03 on the east side of Milne Port in the IPF.

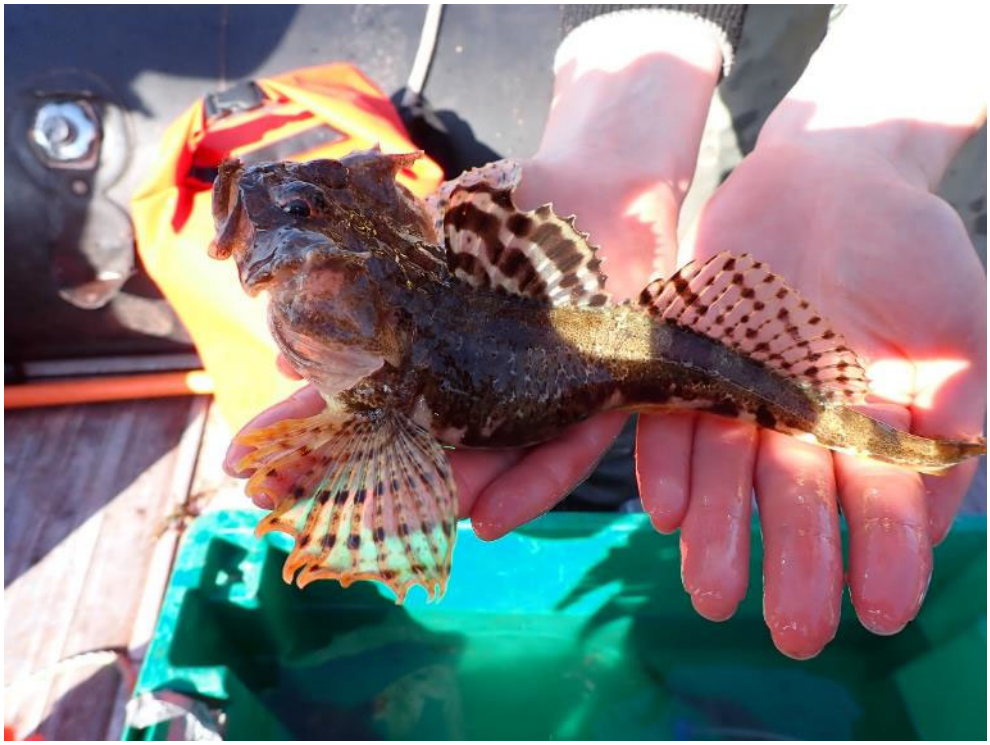

Photo 9: Arctic Staghorn Sculpin (*Gymnocanthus tricuspis*) captured in angling-jigging effort ANJ06 in the fish health reference area.

Photo 10: Ribbed Sculpin (*Triglops pingelii*) captured in trawling effort TR01 in the DPF.

Photo 11: Pacific Cod (*Gadus macrocephalus*) captured in angling (jigging) effort ANJ12 in the IPF.

Photo 12: Arctic Alligatorfish (*Aspidophoroides olrikii*) captured in trawling effort TR01 in the DPF.

Photo 13: Arctic Sculpin (*Myoxocephalus scorpioides*) captured in gill net effort GN18 in the fish health reference area.

Photo 14: Spatulate Sculpin *(Icelus spatulata*) captured in trawling effort TR02 in the DPF.

Photo 15: Unidentified juvenile cod (*Gadus* sp.) captured in trawling effort TR04 in the IPF.

Photo 16: Atlantic Spiny Lumpsucker (*Eumicrotremus spinosus*) captured in trawling effort TR04 in the IPF.

[1] Both *Ammodytes hexapterus* and *A. dubius* occur in the Project Area but are difficult to resolve in the field. *Ammodytes* spp. represents observations for both species.
[2] For the Unidentified Sculpin captured in 2021, taxonomic lab results (Biologica) determined the majority of the fish to be in the genus *Myoxocephalus*. The species identification was unknown; however, results suggest it was potentially *M. aenaeus*. Nine of the unidentified sculpins were only able to be taxonomically identified to genus *Triglops*; results suggest it was potentially *T. pingelii.*
[3] Fish species *Arctogadus glacialis* and *Boreogadus saida* both use the common name Polar Cod. The 2018 report (Golder 2019) indicated an Arctic Cod was captured, referred to as *A. glacialis*. Review of the catch record and field photographs indicate this was actually *B. saida* and was corrected in the 2020 MEEMP report (Golder 2021).
[4] Recent taxonomic changes to the genus *Gadus* have combined species *G. ogac* (Greenland Cod) and *G. macrocephalus* (Pacific or Alaska Cod) under the umbrella term *G. macrocephalus*. A universal edit has been made to change Greenland cod (*G. ogac*) to Pacific Cod (*G. macrocephalus*).
[5] For the Unidentified Cod captured in 2023, taxonomic lab results (Biologica) were determined to be in the genus *Gadus*.
[6] Taxonomic lab results (Biologica) identified the 2021 Unidentified Snailfish from Genus *Liparis*. The species was determined be either *L. gibbus* or *L. tunicatus*, however identifying features were not clear.
[7] Note, taxa richness is based on known taxa, therefore 'unidentified' taxa were removed from the taxa richness calculation. This change was made in 2023 and corrected for previous years.

APPENDIX E

Power Analysis

POWER ANALYSIS – FISH COMMUNITY CPUE

This section presents the results of a power analysis undertaken for the 2020 to 2023 fish community program in support of the catch-per-unit-effort (CPUE) statistical analyses.

METHODS

A Type I error is concluding there is a significant effect when none exists (i.e., a false positive). Alpha (α) is the probability of committing a Type I error. A Type II error is the probability of concluding there is no significant effect when there is a real effect of some specified magnitude (i.e., a false negative). Beta (β) is the probability of committing a Type II error. The power of a statistical test (1 - β) is the probability of detecting a real effect.

In this analysis, the Type I error-rate (α), also referred to as the significance level, was set to 0.05. The desired minimum statistical power was 80%, which corresponds to a type II error-rate of 0.2. Power analyses were conducted to assess the power of statistical tests under three effect sizes – detection of a reduction of 20%, 30%, and 40% in catch per unit effort in the DPF relative to the IPF area in 2023. A range of sample sizes was assessed for each gear type, to evaluate whether increasing effort within the logistical constraints associated with the sampling would result in sufficient (>80%) statistical power.

Data Simulation following Effect Size Application

The power to detect statistically significant effects was estimated using residual bootstrapping in R v. 4.3.2 (R 2023), following the approach of Fox and Weisberg (2018). The general approach was to simulate data based on the model selected for interpretation, the observed sample size (or the sample size of choice), and the variability estimated by the original model, and re-run the models that were used for the original analysis using the simulated data. The data simulation and analysis were repeated 5,000 times, and the proportion of repetitions where the *P*-values of interest were significant ($P<0.05$) was interpreted as the statistical power of the test.

To produce simulated data, the original model was used to predict values of the response variable, and the dispersion estimated by the original negative binomial model were calculated and retained. The predicted values were then adjusted according to the effect size, depending on analysis (see below for details). For each iteration of the simulation, the adjusted predicted values and the dispersion from the original model were used to generate a randomly drawn sample of negative binomial counts, to produce a set of simulated data. Generating the randomly drawn sample around the effect size-adjusted predictions was done to create a level of variability in the simulated data that was similar to the observed data. The simulated data were then analyzed using the same model structure as the original analysis.

In the analysis of 2020 to 2023 data, the question of interest was a reduction in fish CPUE between DPF and IPF in 2023. That is, the power to detect the interaction between area and sampling year needed to be assessed. In addition, the power of the multiple comparisons between areas within year was of interest, specifically for the comparison between 2023 and 2022, relative to which effect sizes were applied. The effect was applied as percentage relative to the values predicted for the IPF in 2023. That is, an increasing effect size resulted in a larger difference between the IPF and DPF areas in 2023.

The power to detect a significant main effect of year on an interaction between year and area was assessed, as well as the power to detect a difference between 2022 and 2023 in the subsequent multiple comparisons. The effect was applied as percentage relative to the values predicted for 2022. That is, an increasing effect size

resulted in a larger difference between 2022 and 2023. The simulated data were analyzed using the same model as the original analysis described in the main report, and the *P*-values for the effects of interest were retained, which included both the main effect of area and an interaction with area (for models that included at interaction). If any of these *P*-values were less than 0.05, it was considered a statistically significant result. The proportion of repetitions with *P*-values less than 0.05 was interpreted as the statistical power of the overall regression for that effect size. In addition to the power to detect the interaction between year and area (for models that included an interaction), the power to detect a difference between areas 2023 in the subsequent multiple comparisons was also calculated, where if the *P*-value of the comparison between the IPF and DPF in 2023 was less than 0.05, the comparison was considered significant. For models that did not include an interaction between area and sampling year due to lack of captured fish in some years in the IPF, multiple comparison power was assessed for comparisons between years, where if the *P*-value of the comparison between 2022 and 2023 was less than 0.05, the comparison was considered significant. The power analysis was performed on three effect sizes – CPUE reductions of 20%, 30%, and 40% relative to the IPF, and a range of sample sizes, depending on fishing gear.

Power Analysis – Reporting of Results

Power curves were produced, showing statistical power as a function of sample size and effect size in percentages. Horizontal lines were added to visualize statistical power values of 0.8 (hereafter sufficient power) and 0.9 (hereafter high power), and the observed effect size was provided in the results.

RESULTS

For the analyses of CPUE, only the models that did not have an interaction between year and area (angling-trolling and hoop nets for all species and angling-jigging for Fourhorn Sculpin) had sufficient power to detect the assessed effects given the evaluated sample sizes (Figure 1, Figure 4). For angling-jigging, the observed annual sample sizes were sufficient to detect a 20% reduction in CPUE relative to 2022 for analysis of all species CPUE and Fourhorn Sculpin CPUE, while for all species data from hoop nets, at least 12 sampling efforts were required to achieve sufficient power to detect a 30% to 40% reduction, and at least 13 sampling efforts to detect a 20% reduction (Figure 1). The higher statistical power under observed effect sizes for angling-jigging for Fourhorn Sculpin (Figure 4) was due to some of the annual observed effect sizes being much higher than the smallest sample size - 17 angling-jigging sampling events took place at the DPF in 2020, but only seven in the IPF in 2020, and only five in the IPF in 2022. Hence, the statistical power given observed effect sizes was higher than if all sample sizes had been set to 10.

For the models that had an interaction between year and area (angling-jigging, gill nets, and Fukui traps for all species, gill nets for Fourhorn Sculpin, and gill nets for Arctic Char), none of the assessed sample sizes and effect sizes achieved sufficient statistical power to detect a significant interaction between year and area (Figure 1, Figure 4, Figure 7). None of the multiple comparisons, for all models, had sufficient statistical power to detect as significant post-hoc comparison – between IPF and DPF in 2023 (for models with an interaction; Figure 2, Figure 5, and Figure 8) or between 2022 and 2023 (for models without an interaction; Figure 3 and Figure 6).

The observed effect sizes for the analyzed CPUE data ranged from -96 (for Fourhorn Sculpin sampled in angling-jigging in 2020 and 2022) to +637 (for all species sampled in angling-trolling in 2022 and 2023; Table 1). While observed effect sizes were often large, sample sizes in the dataset were often small and inconsistent between years and areas. For example, 17 angling-jigging sampling events took place at the DPF in 2020, but only seven

in the IPF in 2020, and only five in the IPF in 2022. The inconsistency in sample size likely reduced the statistical power of the analysis for the all-species-combined dataset. The large differences in annual differences between IPF and DPF for Arctic Char (Table 1) resulted in the only significant interaction found in the original analyses.

The low power to detect a significant interaction was due to three main causes –

1) data variability,
2) low CPUE in the IPF, relative to which the reduction was being simulated, and
3) the lack of difference between areas within previous years (hence requiring a very large difference in 2023 to make the overall interaction significant)

On the other hand, the high power to detect a significant effect of year in models without an interaction, even under observed effect sizes, was driven by differences in CPUE in 2020 and 2022 sampling years. For example, angling-trolling for all species combined had low CPUE values in 2020 and high CPUE values in 2022, leading to an existing difference between years, regardless of the simulated effect size.

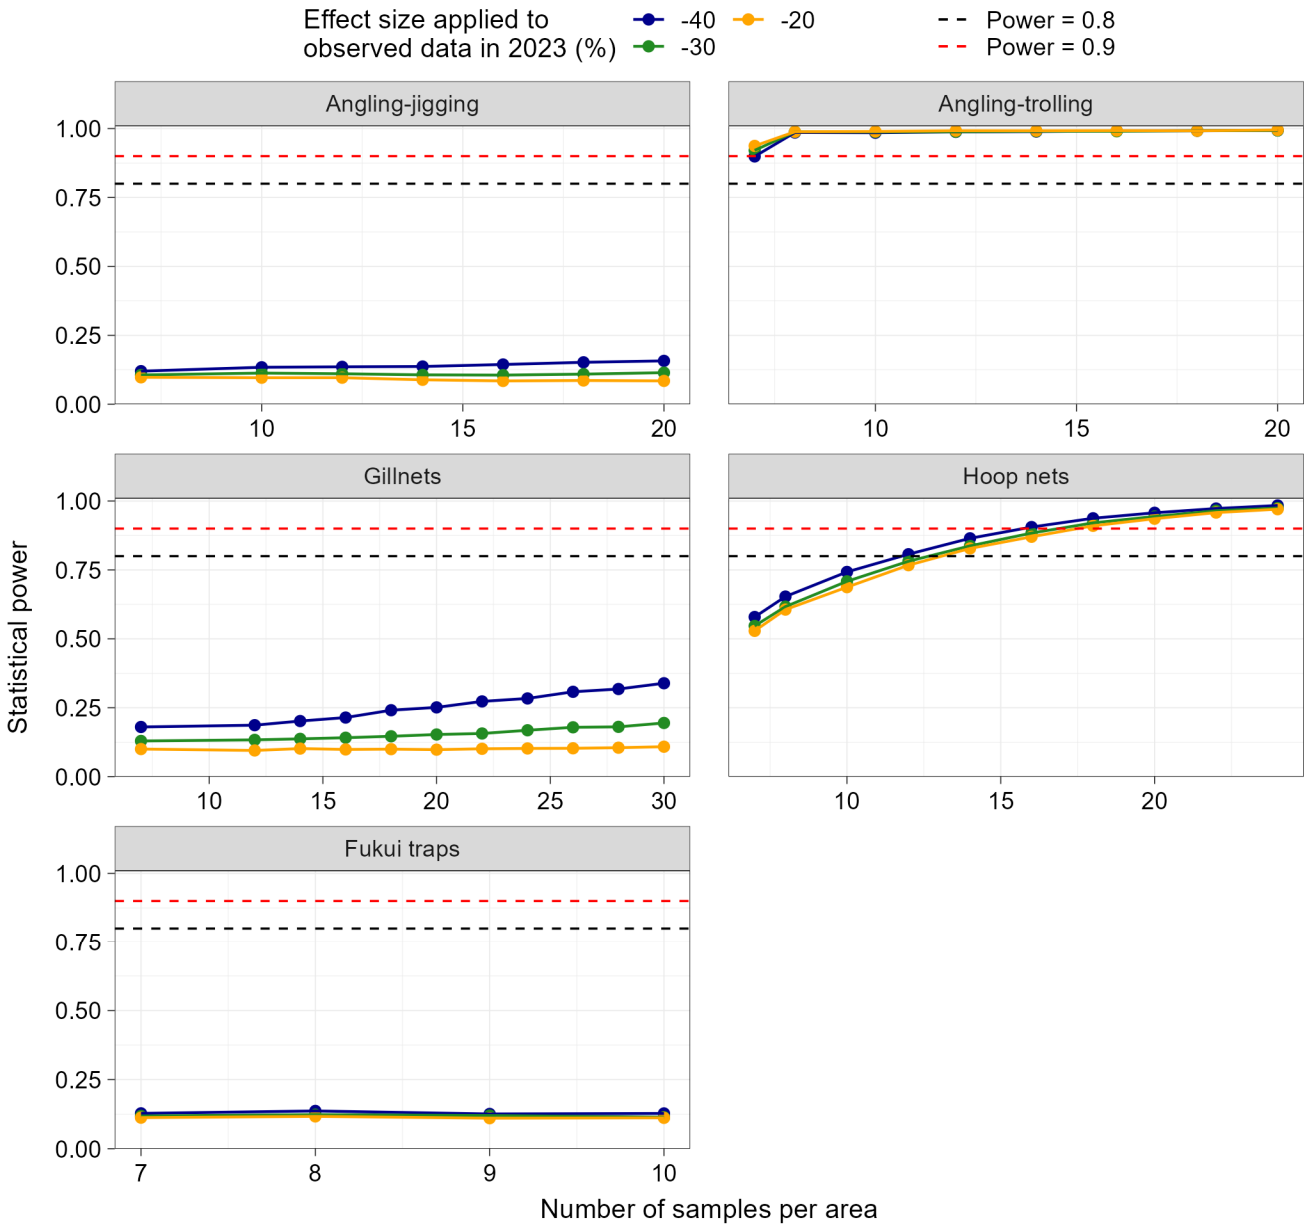

Figure 1: Statistical power of the models of fish CPUE for all species combined to detect a significant interaction between area and year (for models with an interaction) or a main effect of year (for models without an interaction), based on CPUE data collected in 2020 to 2023. The first point on each panel shows power given the observed annual sampled sizes.

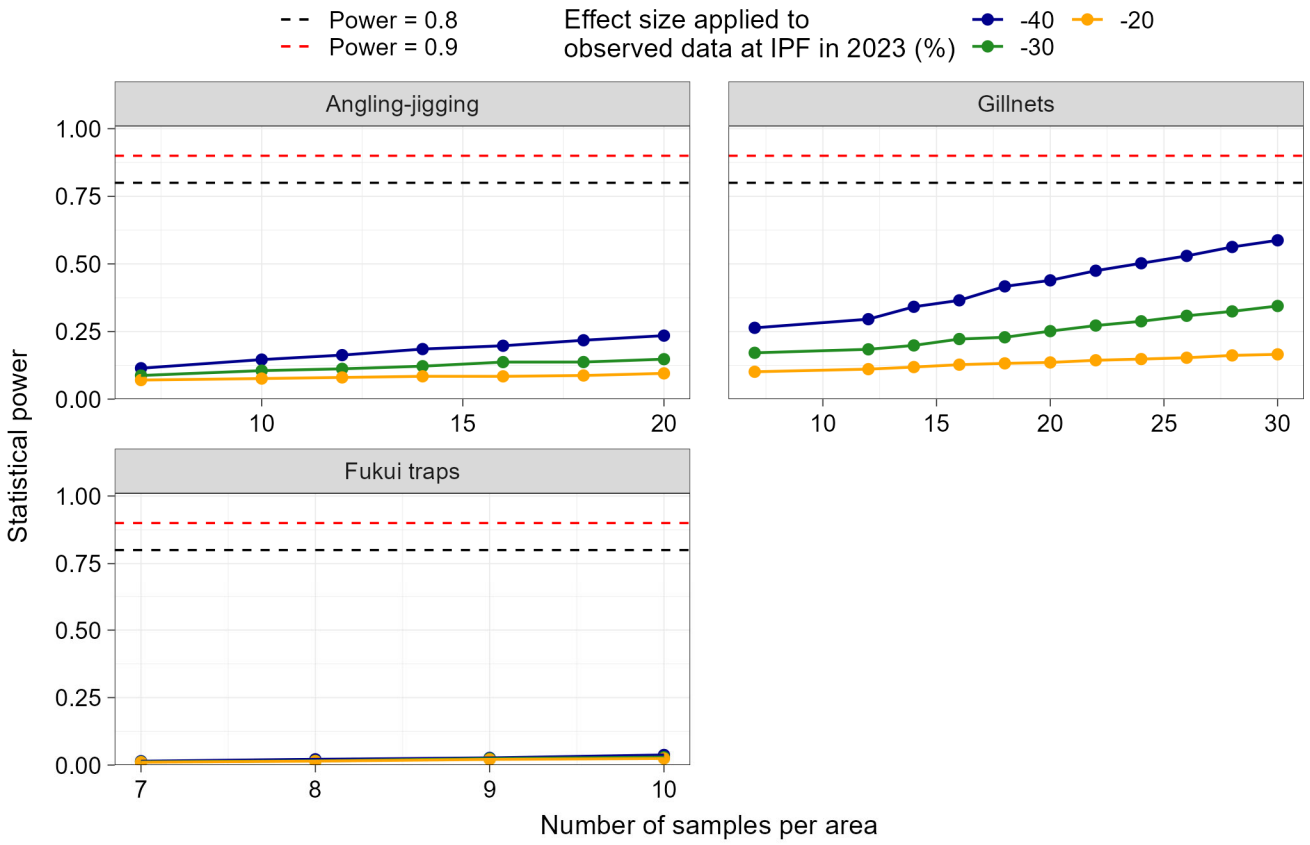

Figure 2: Statistical power of the models of fish CPUE for all species combined to detect a significant post-hoc comparison between IPF and DPF in 2023 (for models with an interaction).

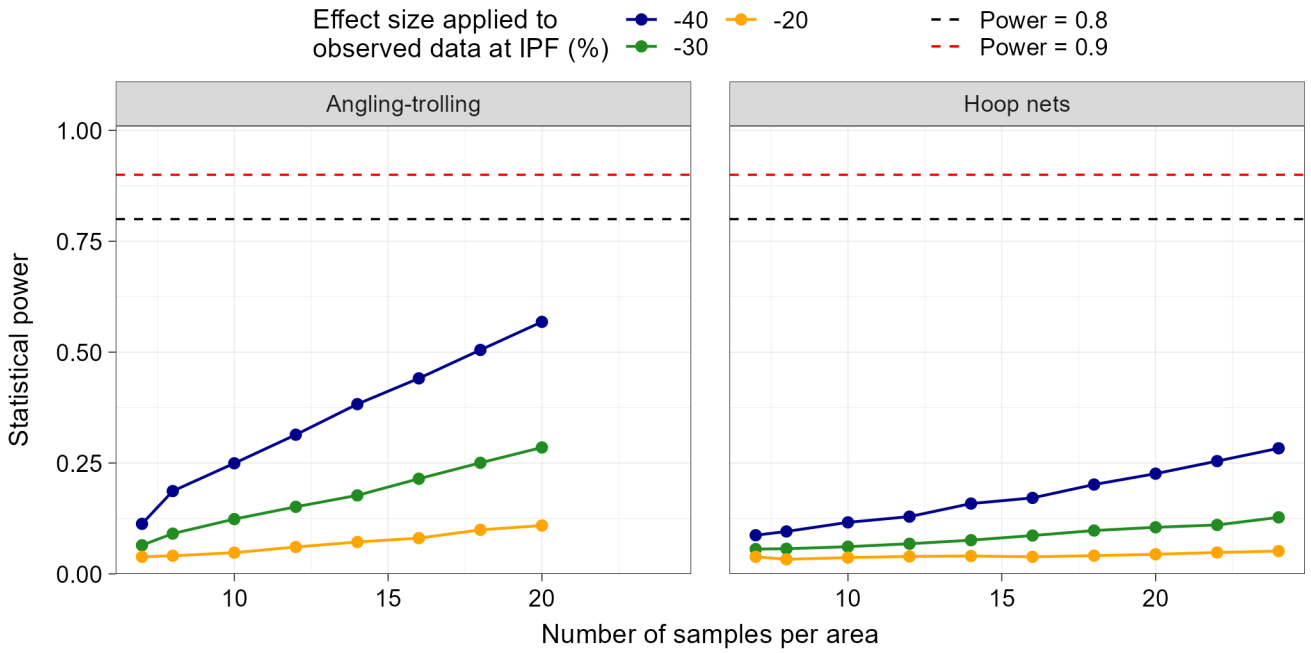

Figure 3: Statistical power of the models of fish CPUE for all species combined to detect a significant post-hoc comparison between 2023 and 2022 (for models without an interaction).

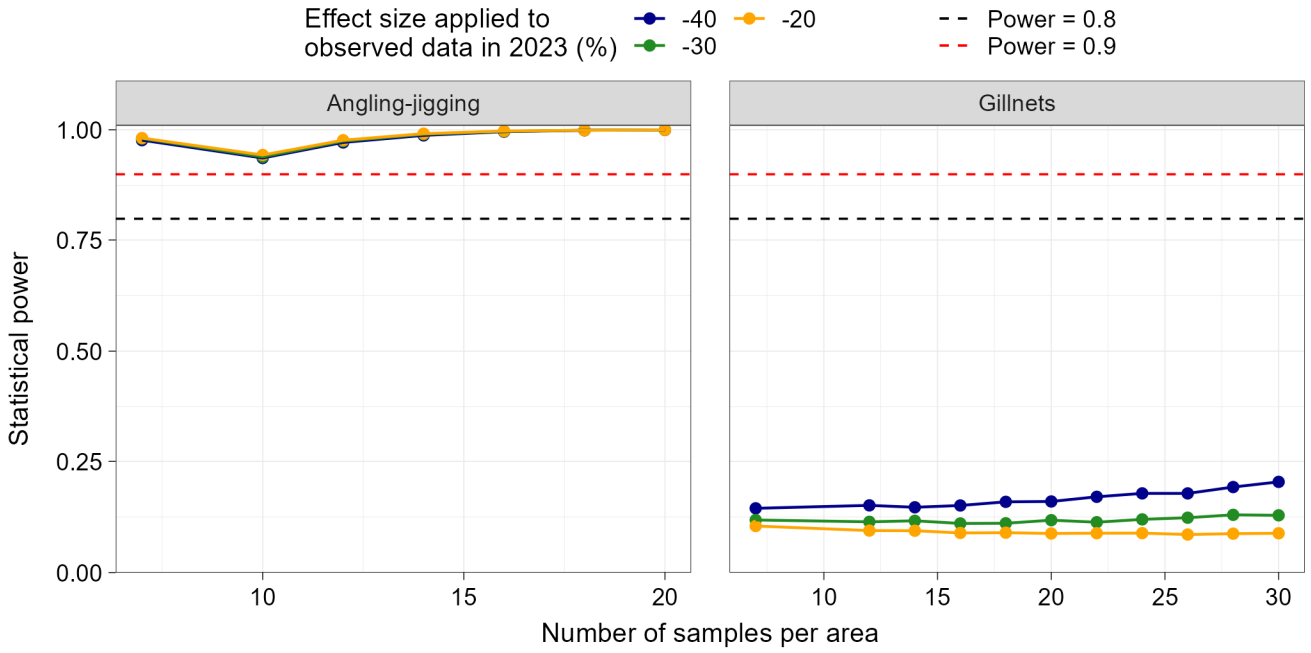

Figure 4: Statistical power of the models of Fourhorn Sculpin data to detect a significant interaction between area and year or a main effect of year based on CPUE data collected in 2020 to 2023.

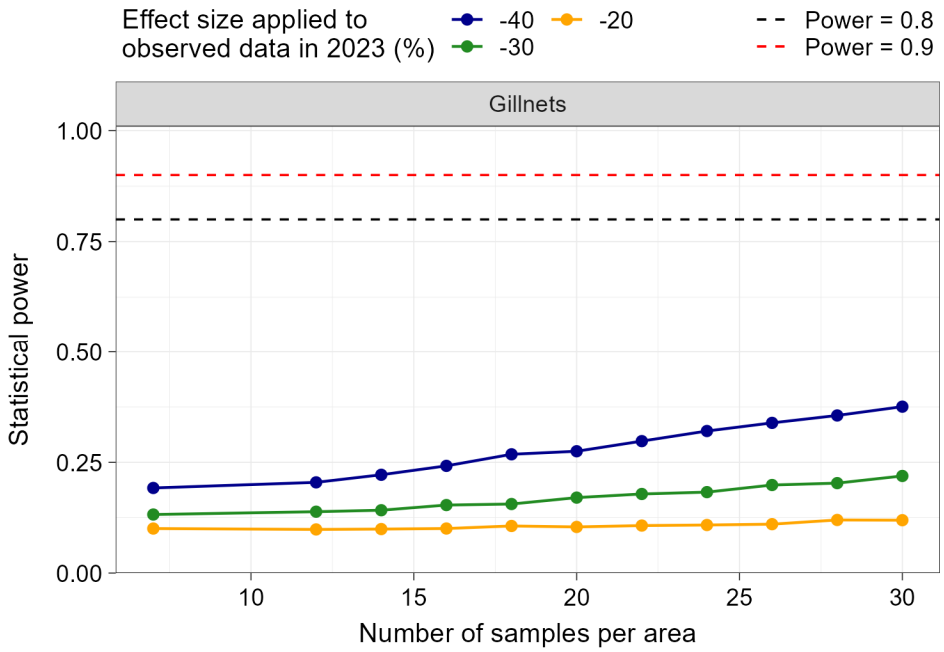

Figure 5: Statistical power of the models of Fourhorn Sculpin data to detect a significant post-hoc comparison between IPF and DPF in 2023 (original model included an interaction).

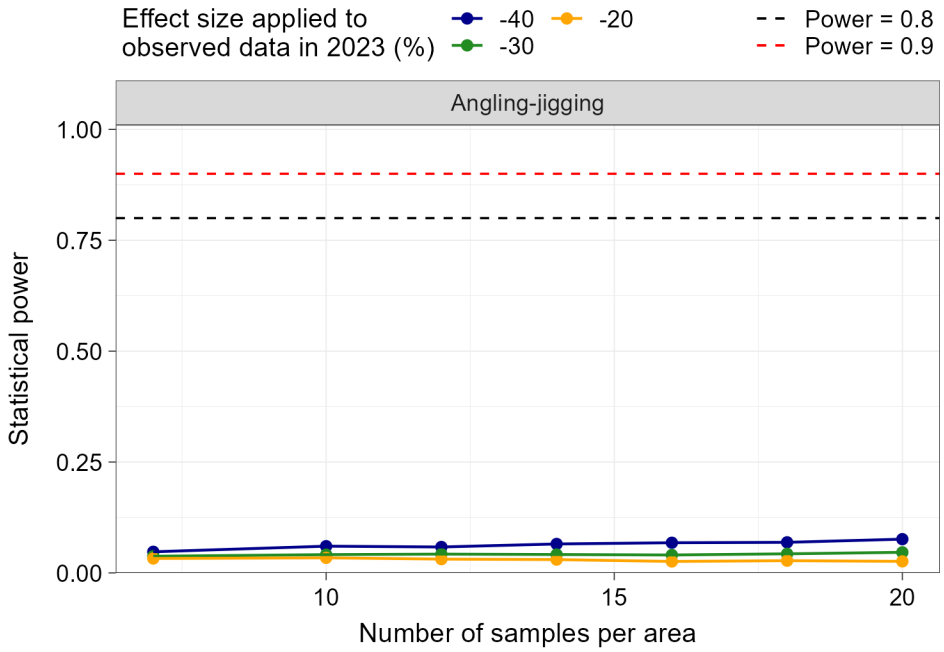

Figure 6: Statistical power of the models of Fourhorn Sculpin data to detect a significant post-hoc comparison between 2023 and 2022 (original model did not have an interaction).

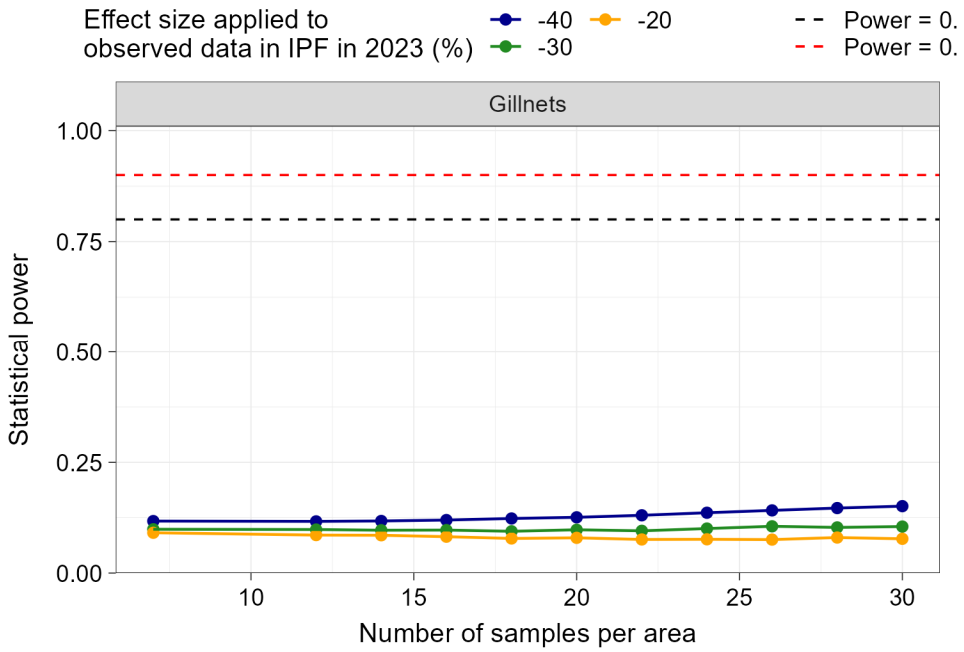

Figure 7: Statistical power of the models of Arctic Char data to detect a significant interaction between area and year based on CPUE data collected in 2020 to 2023.

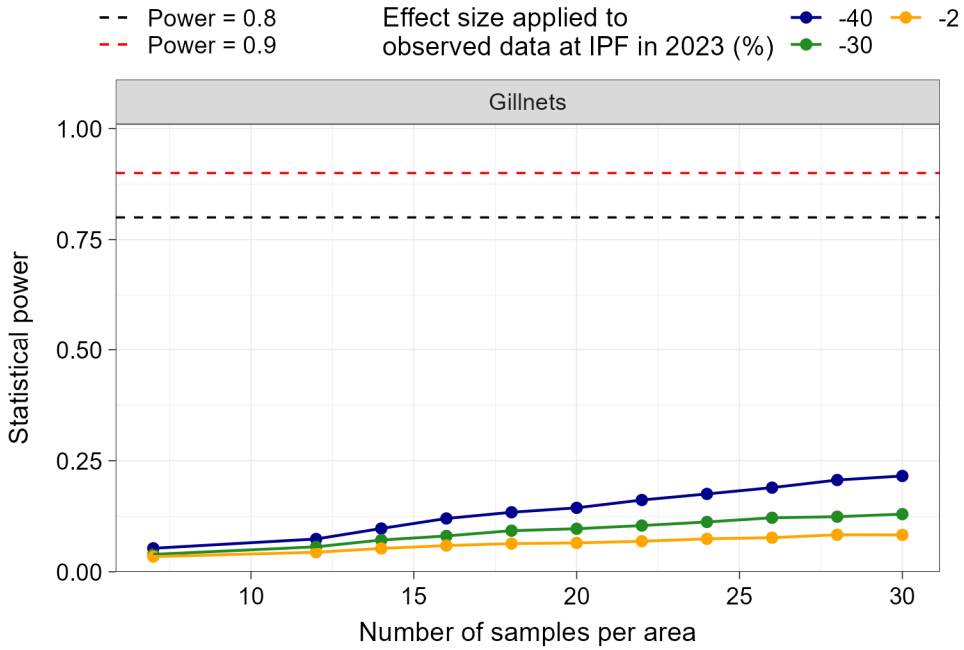

Figure 8: Statistical power of the models of Arctic Chat data to detect a significant post-hoc comparison between IPF and DPF in 2023 (original model included an interaction).

Table 1: Observed effect sizes for analyses of fish CPUE data from 2020-2023.

Species	Gear	Observed effect sizes (%)			
		2020	2021	2022	2023
All fish combined	Angling-jigging (DPF – IPF)	90	20	146	218
	Angling-trolling	Range from -93 (2020 – 2022) to +637 (2022 – 2023)			
	Gill nets (DPF – IPF)	74	99	4	176
	Fukui traps (DPF – IPF)	185	-58	-15	-75
	Hoop nets	Range from -62 (2021 – 2022) to +201 (2020 – 2021)			
Fourhorn Sculpin	Angling-jigging	Range from -96 (2020 – 2022) to +39 (2022 – 2023)			
	Gill nets (DPF – IPF)	462	143	139	218
Arctic Char	Gill nets (DPF – IPF)	-25	67	-37	416

SUMMARY

Overall, statistical power to detect an interaction between year and area was low, while power to detect an overall year effect (for models that did not include an interaction) was high. Across all models, including cases where power was sufficient to detect the overall interaction or main effects, there was not sufficient power to detect a post-hoc difference between areas in 2023 (for models with interaction) or between 2022 and 2023 (for models without an interaction).

Implications of Power Analysis Results

Overall, the results of the power analysis presented here indicate that analyses of fish CPUE data often had low power despite efforts to increase overall sampling size and equalize the sample sizes between the two sampling areas. Given the low statistical power, going forward, it is recommended differences between areas should be assessed using effect sizes rather than a strict adherence to statistical significance.

In order to focus sampling effort on methods that provide the least cases of zero catch, it is recommended to remove Fukui traps and angling-trolling from the sampling design. This simplification of sampling would allow increasing the effort spent on sampling with angling-jigging, gill nets, and hoop nets. The increase in sampling for these 3 methods would allow for an increased statistical power for the respective analyses. Small numbers of trawling efforts would be continued, and as in previous years, would not be statistically analysed.

7.0 FISH HEALTH AND TISSUE CHEMISTRY

7.1 Introduction

This chapter presents the results of the 2023 fish health and tissue chemistry monitoring program, a component of the larger Marine Environmental Effects Monitoring Program (MEEMP) conducted in Milne Inlet during the 2023 open-water season. The fish health and tissue chemistry component was developed in consideration of the potential Project-related impacts to the marine environment as identified in the 2012 Final Environmental Impact Statement (FEIS) and FEIS addenda, as well as monitoring requirements outlined in the Project Certificate (PC) Conditions described in Chapter 1.0, Table 1-2. Those conditions related to the monitoring of fish health include PC Conditions No. 76, 83 (a), 99 (a), 113, and 114: a summary of monitoring components addressing specific PC conditions is presented in Table 7-1.

Table 7-1: Summary of Monitoring Components Addressing Project Certificate (PC) Conditions

PC Condition	Description	Monitoring Component
76	The Proponent shall develop a comprehensive Environmental Effects Monitoring Program to address concerns and identify potential impacts of the Project on the marine environment.	Fish Health & Tissue Chemistry – Spatial and Temporal Comparisons
83(a)	The Proponent shall […] in the Milne Inlet Port area […] determine the potential impacts arising from disturbance to sediments including re-suspension and subsequent transport and deposition of sediment. […]. The monitoring program shall include an ongoing assessment of the potential introduction of metals that bio-accumulate in the marine food chain.	Tissue Chemistry – Temporal Comparisons
87	The Proponent shall develop a detailed monitoring program at a number of sites over the long term to evaluate changes to marine […] organisms […]. This program needs to be able to detect changes that may have biological consequences and […] collect sufficient baseline data and should continue over the life of the Project.	Fish Health & Tissue Chemistry – Temporal Comparisons
99(a)	Establish shipping season, inter-annual baseline in […] Milne Inlet that enables effective monitoring of physical and chemical effects of ballast water releases, sewage outfall, and bottom scour by ship props […]. This shall include the selection and identification of […] biological community/indicator components [… including] both pelagic and benthic species but with emphasis on relatively sedentary benthic species (e.g., sculpins).	Arctic Char (pelagic) Fourhorn Sculpin (benthic) *Hiatella arctica* (benthic) Fish Health & Tissue Chemistry – Spatial and Temporal Comparisons
113	The Proponent shall conduct monitoring of marine fish and fish habitat, which includes but is not limited to, monitoring for Arctic Char stock size and health condition in Steensby Inlet and Milne Inlet, as recommended by the MEWG.	Arctic Char Fish Health – Temporal Comparisons
114	In the event of the development of a commercial fishery in the […] Milne Inlet-Eclipse Sound [area], the Proponent […] shall update its monitoring program for marine fish and fish habitat to ensure that the ability to identify Arctic Char stock(s) potentially affected by Project activities and monitor for changes in stock size and structure of affected stocks and fish health (condition, taste) is maintained to address any additional monitoring issues identified by the MEWG relating to the commercial fishery.	Arctic Char Fish Health – Temporal Components

Project Certificate (PC) Condition descriptions have been edited for conciseness and relevance to Milne Inlet: text that has been edited or removed is indicated using square brackets, […].

MEWG = Marine Environment Working Group.

7.1.1 Objectives

The MEEMP objectives are outlined in Section 1.3 for the overall program. The objectives specific to the fish health and tissue chemistry component are:

- Better align the MEEMP with the Metal and Diamond Mining Effluent Regulations (MDMER) Environmental Effects Monitoring (EEM) program (Government of Canada 2002) through the selection of sentinel species and measurements of additional health indicators to monitor for effects from the Project.
- Evaluate the health of the sentinel species, Fourhorn Sculpin (*Myoxocephalus quadricornis*) and Wrinkled Rock-Borer (*Hiatella arctica*), through the assessment of established endpoints (see Section 7.2), length-frequency distributions, length-weight relationships, and visual assessment of internal and external abnormalities.
- Compile current and previously collected tissue chemistry data for Arctic Char (*Salvelinus alpinus*), Fourhorn Sculpin, and *H. arctica*, and assess concentrations of constituents of potential concern (COPCs) associated with the Project.

In addition, to better align the MEEMP with the MDMER EEM program, reference area reconnaissance surveys have been undertaken to identify a suitable reference area for comparing fish health endpoints with Milne Port (see Appendix 7A).

7.2 Study Design

The fish health and tissue chemistry components of the MEEMP were designed to monitor for potential Project-related impacts and changes to fish health and communities through collection of fish population data. Fish were collected using a combination of active and passive fishing methods, and sentinel species are assessed through health assessments and the analysis of tissue chemistry parameters. Incidental mortalities of Arctic Char are also included in the fish health assessment.

During baseline and early MEEMP surveys, fish tissue sampling was limited to incidental Arctic Char mortalities, the numbers of which fluctuated from year to year and did not always yield adequate samples to support a meaningful statistical analysis. In 2018, a local shellfish species *H. arctica*, was added to the MEEMP as an additional effects indicator for the fish sampling program. *Hiatella arctica* is a resident species in the Project area, easily identifiable and measurable in the field, and abundant in the study area (Golder 2018). Measurement endpoints for *H. arctica* in 2018 and 2019 included age and tissue chemistry analysis.

In 2020, changes to the fish health and tissue chemistry program were implemented to better align the MEEMP with the Metal and Diamond Mining Effluent Regulations (MDMER) Environmental Effects Monitoring (EEM) program (Government of Canada 2002). Fourhorn Sculpin and *H. arctica* were selected as sentinel species to monitor for effects from the Project. Lethal target sample sizes were established for Fourhorn Sculpin and *H. arctica* as part of the 2020 fish health program. Fish health effect indicators included measures of energy use (i.e., growth, reproduction), energy storage (i.e., condition) and survival (i.e., age), in addition to supporting endpoints (as appropriate for each species) such as length, body weight, the prevalence of external and internal abnormalities, organ weights, stomach fullness, parasite presence/absence, sex, life stage, and state-of-maturity

(Section 7.4.1; Appendix 7B). In 2023, relative shell weight was added as an endpoint for *H. arctica* to better align the MEEMP program with MDMER EEM endpoints.

For fish tissue chemistry, concentrations of total metals[1] and polycyclic aromatic hydrocarbons (PAHs) were measured (Section 7.4.2; Appendix 7C) from each species (i.e., Arctic Char, Fourhorn Sculpin, and *H. arctica*) and compared to MEEMP data from previous years, where possible. Historical data available for comparison varied for each species, with data extending intermittently back to 2010 for Arctic Char, and back to 2018 for Fourhorn Sculpin and *H. arctica*.

7.2.1 Modifications to the Program (2023)

In 2023, a reconnaissance survey was undertaken during the August field program to identify a suitable reference area for the fish health and tissue chemistry component of the MEEMP. Sampling effort was focused on the north shore of Koluktoo Bay, similar to reconnaissance work completed in 2022 (WSP 2023). Water quality, sediment quality, and fish community sampling was undertaken as part of the reconnaissance survey and a summary of the methods and results of the 2023 reconnaissance survey is provided in Appendix 7A. Fourhorn Sculpin captured and processed from Koluktoo Bay were used for spatial comparisons for fish health and tissue chemistry endpoints, following guidance for MDMER EEM programs.

Shorthorn Sculpin (*Myoxocephalus scorpius*) were also retained for fish health assessment as a potential sentinel fish species in future programs. Shorthorn Sculpin were collected from the Mine Port area as well as from Koluktoo Bay during the reconnaissance survey. Fish health data for Shorthorn Sculpin are not analyzed herein as they are not currently a sentinel species for the MEEMP, but the data are included in this report (i.e., Shorthorn Sculpin collected from Milne Port are included in Chapter 6.0–Fishing Efforts and Catch Data, while data for Shorthorn Sculpin collected during the reconnaissance survey are included in Appendix 7A) should the species become integrated in the MEEMP in the future.

Previous reconnaissance studies near the Tugaat River estuary indicated there was a sufficient population of *H. arctica* present at this site (Golder 2021). Given previous success, the Tugaat River estuary was deemed a suitable reference are for *H. arctica* for future fish health assessment programs, beginning in 2023.

No other significant modifications were made to the fish health and tissue chemistry MEEMP component in 2023.

7.2.2 Indicators and Thresholds

Along with several other components of the MEEMP, the fish health monitoring program has indicators, thresholds and risk categories that are part of Baffinland's Trigger Action Response Plan (TARP), an adaptive management process. The TARP uses effect indicators that are measured against a series of tiered thresholds (i.e., low, moderate and high-risk thresholds) that are designed to guide short-term and long-term adaptive management strategies as outlined in Baffinland (2024). Baffinland has updated the TARP as part of the revised draft Marine Monitoring Plan (MMP) which will be submitted to the NIRB as part of the SOP2 submission package

[1] Includes metals, metalloids, and non-metals. Metals are broadly defined as elements which are good conductors of electricity and heat, which form cations by loss of electrons, and which yield basic oxides and hydroxides (Wood et al. 2012). Metalloids share some but not all properties of metals, while non-metals mostly lack characteristics of metals.

(Baffinland 2024). The pre-defined actions identified in the TARP describe the responses that Baffinland would implement should the corresponding threshold levels be exceeded and assuming there is some degree of certainty that the measured change is Project-related. As adaptive management is beyond the scope of the present report, only the indicators, risk categories and thresholds are presented here (section 2.3.4).

7.3 Materials and Methods

7.3.1 Sampling Areas

Fish health sampling occurred in 2023 in three main areas: (1) near Milne Port (17W 503700m E, 7976400m N), approximately 80 km Northwest of the Mary River Project, (2) in Koluktoo Bay, and (3) in Tugaat River Estuary. The latter two areas represent two proposed reference areas to support the fish health program of the MEEMP.

Milne Port is located at the southern end of Milne Inlet. The port is located in a narrow fjord, surrounded by relatively steep, bedrock slopes. Fish habitat is composed mainly of coarse rock substrates (i.e., boulders with sparse cobbles) nearby the Ore Dock and open-water habitat. Sculpin species, including Fourhorn and Shorthorn sculpin, are relatively abundant at Milne Port, as are Arctic Char (see Chapter 6.0 for further information).

The reference area for finfish was located in Koluktoo Bay (17X 506100m E, 7997100m N), approximately 20 km north of Milne Port. The Robertson River feeds into Koluktoo Bay along the western shore, which has formed a relatively large, sandy delta. The remainder of the bay is bordered by gently sloping bedrock to the north, and steeper bedrock slopes to the south. Fish habitat is composed of a mixture of coarse rocks, cobbles, and fine sediments, comprising long, shallow, sandy littoral habitat and boulder/cobble reefs, prior to dropping off into deeper habitat. Previous reconnaissance surveys captured Shorthorn Sculpin and Arctic Sculpin (*Myoxocephalus scorpioides*) in Koluktoo Bay (WSP 2023).

The reference area for shellfish was located near the Tugaat River estuary (17X 522700m E, 7996700m N), approximately 28 km northeast of Milne Port, where the Tugaat River enters Milne Inlet. Substrates near the Tugaat River estuary were primarily fine sediments, being mainly composed of sand with some cobble. Field Methodology

Finfish

Finfish community sampling was conducted at various locations near Milne Port and along the north shore of Koluktoo Bay, from 28 July to 12 August 2023 (Figure 6-1 to Figure 6-5). Fishing effort included both active (i.e., angling by jigging and trolling, and trawling) and passive (i.e., Fukui traps, hoop nets, and gillnetting) capture methods. Captured fish were enumerated and measured for length and weight. Capture methods are described in detail in Section 6.3.1 of Chapter 6.0.

At Milne Port, a subsample of 40 Fourhorn Sculpin were retained for fish health sampling to meet target sample sizes of 20 adult males and 20 adult females. Captured Arctic Char were processed as part of the Marine Fish Community Program (Chapter 6.0). Incidental mortalities of Arctic Char were retained for analysis of age, stomach contents, and tissue metals concentrations. Results of these analyses for Arctic Char are presented herein, with biometric measurements included, where relevant, as supporting information. At Koluktoo Bay, all Fourhorn Sculpin captured were retained for fish health sampling, resulting in a total of 25 fish retained (18 female and seven male). All other fish, aside from Shorthorn Sculpin (per Section 7.2.1), were released alive back to Milne Inlet at their location of capture.

The primary method of capture for Fourhorn Sculpin in 2023 was angling. Angling (i.e., jigging) efforts were focused on the western and eastern sides of the Ore Dock in coarse rock habitat at depths between 1 m and 5 m (consistent with previous years). Fishers fished from a stationary position, with two to five rods and lines deployed from the field vessel anchored adjacent to the riprap. Hooks or spoon lures (i.e., flashers) were lowered into the riprap at the target depth, then flicked upward to attract fish within the coarse rock habitat.

Shellfish

Hiatella arctica were collected opportunistically from benthic infauna samples, with a target subsample of 40 individuals retained from each sampling area for fish health and tissue chemistry sampling. Benthic infauna samples were collected from the Milne Port area and from the Tugaat River estuary reference area. Collection methods for benthic infauna are described in Section 4.3.1 in Chapter 4.0. Each benthic sample was checked for the presence of *H. arctica*. In Milne Port, samples to be retained for the fish health and tissue chemistry program were obtained from benthic grab samples collected from the northwestern, western, eastern, and northeastern transects (Figure 3-1), with the majority of collections occurring from the western and eastern transects. For both sampling areas, a maximum of five individuals were selected when benthic grab samples contained the greatest numbers of *H. arctica*. Specimens were selected for processing if the shell was intact, greater than 15 mm in length, and had no indications of damage to the umbo or hinge area.

7.3.1.1 Fish Processing

Fourhorn Sculpin retained for fish health sampling were held live in aerated 70 litre totes containing water from Milne Inlet until they were lethally processed at Milne Port. Both external and internal assessments were completed on lethally sampled fish following standardized procedures consistent with MDMER EEM program requirements (Environment Canada 2012). Total lengths (± 1 mm) and total body weights (± 0.001 g) of the fish were documented, and external observations of fish features (i.e., body form, eyes, skin, thymus, opercula, gills, pseudobranchs, fins, vent, and parasites) were recorded. Abnormal features (e.g., wounds, tumours, parasites, fin fraying, gill parasites, or lesions) were documented and photographed. Fish were sacrificed by a concussive blow to the head followed by cervical dislocation (i.e., cutting the spinal cord behind the head). Each fish was handled using new nitrile gloves and dissected on a cutting board covered in a clean sheet of plastic wrap that was changed between fish. The condition of the internal organs (e.g., liver, spleen, gall bladder, and kidneys) was assessed immediately after opening the body cavity and documented. Any abnormalities in size, shape, or colouration of the internal organs were documented. Liver weight and an estimate of percent mesenteric fat were recorded. The gonads of each fish were removed, weighed (± 0.001 g), and photographed before assigning sex and maturity stage, based on the macroscopic features described in Table 7-2. Parasite presence and predominance were recorded, and parasite weight was documented if large parasites (e.g., tapeworms) were observed in the body cavity.

Stomachs and ageing structures (i.e., otoliths[2]) were collected from Fourhorn Sculpin and incidental mortalities of Arctic Char. Sagittal otoliths were extracted as the primary aging structure, wrapped in parchment paper, and stored dry in individually labelled coin envelopes until submission for aging analysis. Stomach fullness was recorded, and the stomachs were removed, placed in individually labelled Nalgene containers, and preserved with

[2] Otoliths are paired bony structures located behind the eyes in fish. Counting the annual growth rings on the otoliths is a common technique in estimating the age of many fish species.

10% formalin. For Fourhorn Sculpin and Arctic Char, one muscle sample (> 10 g) without skin was collected from the left dorsal side of each fish using a fillet knife rinsed with 10% nitric acid then deionized ultrafiltered water. The fillets were weighed (± 0.001 g), placed on ice in individually labelled Ziploc bags, and stored frozen until submission for metals analysis. A second muscle sample (> 10 g) without skin was collected from the right dorsal side of each fish using a fillet knife rinsed with acetone then deionized ultrafiltered water. The fillets were weighed (± 0.001 g) on tared aluminum foil, wrapped in aluminum foil, placed on ice in individually labelled Ziploc bags, and stored frozen for PAH analysis.

Those *H. arctica* retained for fish health sampling were selected based on the external condition of the shell (i.e., > 15 mm long with intact valves and no visible damage to the umbo). Individuals were measured along the largest axis (± 1 mm) and weighed (± 0.001 g), and then placed on ice in individually labelled Ziploc bags and stored frozen until submitted for further processing and tissue chemistry analysis.

Table 7-2: Gonad Maturity Stages for Male and Female Fish Used During the Fish Health Assessment, 2023

Sex	Stage	Code	Macroscopic features
Female	Unknown stage	10	Unable to determine stage.
	Immature	11	Small ovaries, often clear, blood vessels indistinct.
	Early Stage Development	12	Enlarging ovaries, blood vessels more distinct. Granular in appearance.
	Late Stage Development	13	Large ovaries filling the body cavity, prominent blood vessels. Individual oocytes visible.
	Ripe	14	Eggs released with gentle pressure on abdomen.
	Spent	15	Deflated ovaries, blood vessels prominent.
	Reabsorbing	16	Small atretic oocytes throughout the ovaries, which are hard and white.
	Resting	17	Small ovaries, blood vessels reduced but present.
Male	Unknown stage	20	Unable to determine stage.
	Immature	21	Small testes, often clear and threadlike.
	Early Stage Development	22	Small testes, semi-translucent, but easily identified.
	Late Stage Development	23	Testes large, firm, and lobate. White to purplish in colour. Granular appearance.
	Ripe	24	Milt released with gentle pressure on abdomen.
	Spent	25	Small and deflated testes. Blood vessels obvious. Violet-pink in colour.
	Reabsorbing	26	Not typically observed in males.
	Resting	27	Small testes, often threadlike.

Notes: Table modified from Brown-Peterson et al. (2011).

7.3.2 Laboratory Methodology

Samples collected from both fish species and *H. arctica* were submitted for further laboratory analysis. Finfish species (i.e., Arctic Char and Fourhorn Sculpin; Section 7.3.3.1) tissue samples were submitted for tissue chemistry analysis, and stomachs were submitted for contents analysis. Ageing structures from both finfish species were submitted for age determination. Collected *H. arctica* (i.e., whole animals) were sent to a laboratory specialized in marine invertebrates (Biologica Environmental Services Ltd., Victoria, BC [Biologica]) for additional processing (Section 7.3.3.2) and subsequent submission of tissues for tissue chemistry analysis.

7.3.2.1 Finfishes

7.3.2.1.1 Age

Otoliths extracted from Fourhorn Sculpin, and Arctic Char were examined by North/South Consultants Inc. (Winnipeg, MB) to determine the age of the fish. Whole otoliths from individual fish were mounted on microscope slides to estimate age based on the number of annuli (i.e., growth rings) visible under a dissecting microscope. To verify that data quality objectives were met, 10% of fish age estimates were independently verified by a second qualified biologist.

7.3.2.1.2 Stomach Contents

Enumeration and taxonomic identification of stomach contents for Arctic Char and Fourhorn Sculpin were conducted by Biologica. Percent fullness and percent digestion was recorded for each stomach before dissection and identification based on the professional judgement of the taxonomist. Prey items were identified to the lowest practical taxonomic level (e.g., species when possible) using published methods and taxonomic references. Digested and unidentifiable materials were categorized (e.g., unidentified insect parts, digested tissue, non-food, and others). The taxonomic composition within each stomach was determined as percentages of major invertebrate groups by abundance. Results are provided in Appendix 7B in Tables 7B-104 and 7B-5.

7.3.2.1.3 Tissue Chemistry

Muscle tissue samples collected from eight Arctic Char and eight Fourhorn Sculpin from the Milne Port area, and samples collected from eight Fourhorn Sculpin from the Koluktoo Bay reference area, were submitted to Bureau Veritas Laboratories (BV Labs; Burnaby, BC) for tissue chemistry analyses (Appendix 7C, Table 7C-1). Moisture content and metals concentrations for fish were measured in percent and milligrams per kilogram (mg/kg) ww, respectively. Moisture content was determined by oven drying and metals concentrations were determined by collision reaction cell inductively coupled plasma mass spectrometry. Concentrations of PAHs for fish were measured in mg/kg ww by gas chromatography mass spectrometry. Achieved detection limits (DL) for fish are presented in Appendix 7C, Tables 7C-3, 7C-4, 7C-6, and 7C-7 and certificate of analysis forms are provided in Appendix 7E.

7.3.2.2 Shellfishes

7.3.2.2.1 Processing

Frozen *H. arctica* were processed by Biologica. *Hiatella arctica* were measured for total length, total width, and total weight, as well as wet weight (ww) of the whole organism, shells, soft tissues, and gonads. Shell dry weight (dw) was also measured. Ages of *H. arctica* were determined using shells (Section 7.3.2.2.2).

7.3.2.2.2 Age

For *H. arctica* ageing, each shell was sectioned through the umbo-rim axis using a lapidary saw with a diamond-impregnated blade and polished using progressively finer grit sandpaper. Polished shells were etched in a solution of 1% hydrochloric acid for one minute, rinsed with tap water, and dried. An acetate peel of the polished umbo surface was mounted on a slide and examined using a dissecting microscope. Distinct, continuous growth lines were counted to determine the age of the shell. To verify that data quality objectives were met, 10% of *H. arctica* age estimates were independently verified by a second qualified biologist.

7.3.2.2.3 Tissue Chemistry

A total of eight *H. arctica* composite soft tissue samples were submitted to BV Labs for tissue chemistry analyses (Appendix 7C, Table 7C-1). *Hiatella arctica* composites were composed of two to three individuals to satisfy weight requirements for metals analysis (Appendix 7C, 7C-2). For PAH analysis, *H. arctica* composite samples comprised four to six individuals to satisfy weight requirements (Appendix 7C, 7C-2). Concentrations of metals and PAHs and the percent moisture content were determined using methods described in Section 7.3.2.1.3. Achieved DLs for *H. arctica* are presented in Appendix 7C, Tables 7C-5 and 7C-8. Certificate of analysis forms are provided in Appendix 7E.

7.3.3 Data Analysis

Descriptive statistics (i.e., sample size, mean, median, standard deviation [SD], standard error [SE], minimum, and maximum values) were calculated for fish health and tissue chemistry data collected in 2023, as well as fish health endpoints and tissue concentrations of metals and PAHs in Arctic Char, Fourhorn Sculpin, and *H. arctica* available from 2018 to 2022.

Fish health indices for Arctic Char and Fourhorn Sculpin were calculated as follows:

$$Condition\ factor = \left(\frac{total\ weight}{total\ length^3}\right) \times 100{,}000$$

Additional fish health indices calculated for Fourhorn Sculpin were as follows:

$$Gonadosomatic\ index\ (GSI) = \left(\frac{gonad\ weight}{total\ weight}\right) \times 100$$

$$Liver\ somatic\ index\ (LSI) = \left(\frac{liver\ weight}{total\ weight}\right) \times 100$$

Fish health indices for *H. arctica* were calculated as follows:

$$Condition\ factor = \left(\frac{total\ wet\ weight}{total\ length^3}\right) \times 10{,}000$$

$$Mantle\ somatic\ index\ (MSI) = \left(\frac{gonad\ wet\ weight}{soft\ tissue\ wet\ weight - gonad\ wet\ weight}\right) \times 100$$

Weight and length measurements were reported in units of grams (g) and millimetres (mm), respectively. For Arctic Char, total length measurements were not collected in 2022. Therefore, total lengths were estimated using fork length-total length formulas in Peet (1978).

7.3.3.1 Fish Health Endpoints

For Fourhorn Sculpin and *H. arctica,* fish health endpoints were compared using statistical methods. Comparisons were completed temporally (i.e., among years for the Milne Port) and spatially (i.e., between the Milne Port and the references areas in 2023).

Finfish

Condition factor comparisons for Arctic Char were conducted by pooling sexes and life stages (i.e., juvenile, adult) to detect potential differences between 2021, 2022, and 2023 because sex and life stage was inconsistently assigned in previous sampling years. Difference in condition factor was assessed using analysis of variance (ANOVA). Data were log_{10}-transformed prior to analysis if it increased the coefficient of determination (R^2) and/or satisfied model assumptions. For Fourhorn Sculpin, comparisons were conducted separately by sex for the health endpoints presented in Table 7-3 to detect potential differences between 2020, 2021, 2022, and 2023 at Milne Port, and differences between Milne Port and Koluktoo Bay in 2023. Differences in age were assessed using ANOVA. Differences in mean size-at-age, condition, relative liver weight, and relative gonad weight among years were assessed using analysis of covariance (ANCOVA). Data analyzed by ANCOVA were log_{10}-transformed prior to analysis if it increased the coefficient of determination (R^2) and/or satisfied model assumptions. Significant differences between years were determined using an alpha (α) of 0.10 (i.e., *P*-values ([*P*] < 0.1 were considered significant). Post hoc comparisons for ANOVA and ANCOVA models were completed using Tukey's Honest Significant Difference test, with *P*-values adjusted for multiple comparisons (Tukey 1977).

Table 7-3: Statistical Procedures Used to Evaluate Fourhorn Sculpin Health Indicators

Indicator	Endpoint	Response Variable (y)	Covariate (x)	Statistical Procedure
Survival	Age	Age	n/a	ANOVA
Growth	Size-at-Age	Total Weight	Age	ANCOVA
Condition	Condition	Total Weight	Total Length	ANCOVA
	Relative Liver Weight	Liver Weight	Total Weight	ANCOVA
Reproduction	Relative Gonad Weight	Gonad Weight	Total Weight	ANCOVA

ANOVA = analysis of variance; ANCOVA = analysis of covariance.

Shellfish

For *H. arctica*, statistical comparisons were conducted for fish health endpoints presented in Table 7-4 to detect potential differences between 2020, 2021, 2022, and 2023 at Milne Port, and differences between Milne Port and Koluktoo Bay in 2023. The differences in length-frequency distributions among years were assessed using the non-parametric two-sample Kolmogorov-Smirnov (K-S) test. The K-S test compares the cumulative relative distributions of total length between years by comparing the maximum percent difference between the two cumulative relative frequency distributions to a critical value. The test assesses whether the maximum percent difference is large enough to indicate that the two distributions are from different populations. K-S test *P*-values were adjusted using Holm's correction for multiple comparisons (Holm 1979). Differences in total weights (i.e., whole animal ww) were assessed using ANOVA. Differences in condition endpoints were assessed using ANCOVA. Differences in relative gonad weights were assessed between 2021, 2022, and 2023, as gonad tissues were not weighed in 2020. Data analyzed by ANCOVA were $\log_{10}$ transformed prior to analysis if it increased the coefficient of determination (R^2) and/or satisfied model assumptions. Significant differences between years were determined using an α of 0.10 (i.e., $P < 0.1$ was considered significant). Post hoc comparisons for ANOVA and ANCOVA were completed using Tukey's Honest Significant Difference test, with *P*-values adjusted for multiple comparisons (Tukey 1977).

Table 7-4: Statistical Procedures Used to Evaluate *Hiatella arctica* Health Indicators

Indicator	Endpoint	Response Variable (y)	Covariate (x)	Statistical Procedure
Survival	Length-frequency	Total Length	n/a	K-S test[(a)]
Growth	Total Weight (whole animal wet weight)	Total Wet Weight	n/a	ANOVA
Condition	Condition	Total Wet Weight	Total Length	ANCOVA
	Relative Shell Weight	Dry Shell Weight	Total Length	
Reproduction	Mantle Somatic Index	Gonad Weight	Tissue Wet Weight	ANCOVA

K-S test = Kolmogorov-Smirnov test; ANOVA = analysis of variance; ANCOVA = analysis of covariance; n/a = not applicable.
(a) *P*-values were adjusted using Holm's correction for multiple comparisons (Holm 1979).

7.3.3.2 Tissue Chemistry

The COPCs for the MEEMP fish tissue chemistry component are based on the primary constituents of the Project iron ore (i.e., aluminum, magnesium, and iron), as well as metals with existing regulatory guidelines for fish tissue (i.e., mercury and selenium). Differences in COPC concentrations were compared among years (i.e., 2018 to 2023) and, for Fourhorn Sculpin, between Milne Port and Koluktoo Bay in 2023. Values below DL were substituted with half the DL and included in statistical comparisons (US EPA 1998).

Trends in aluminum, magnesium, and iron were compared over years using linear regression, and between sampling areas in 2023 using analysis of variance (ANOVA). Trends in tissue concentrations of mercury and selenium in Arctic Char and Fourhorn Sculpin were compared over years and between sampling areas in 2023 using analysis of covariance (ANCOVA), with fish length as a covariate. Trends in mercury and selenium concentrations were evaluated using least square mean concentrations, calculated during ANCOVA analysis. If length was found not to be significantly related to mercury or selenium concentrations, the covariate was removed

and the analytical method was reduced to either a linear regression, for evaluation of trends over sampling years, or to an ANOVA, for comparisons among sampling areas in 2023. For *H. arctica,* length was not a significant predictor of tissue concentrations of mercury and selenium (i.e., the linear regression relationship was not significant), therefore, comparisons were made among years, and among sampling areas in 2023, using ANOVA. Post hoc comparisons for ANOVA and ANCOVA were completed using Tukey's Honest Significant Differences test, with *P*-values adjusted for multiple comparisons (Tukey 1977). Significant temporal trends and differences between sampling areas were determined using an α of 0.10 (i.e., $P < 0.1$ was considered significant).

Tissue chemistry data were presented visually using boxplots, where the median value was indicated within each box and the first and third quartiles were represented by the lower and upper bounds of each box, respectively. Lower and upper whiskers were calculated as 1.5 times the interquartile range beyond the first and third quartile. Observations outside the upper and lower whiskers were plotted as individual points. Whiskers were extended to the minimum and maximum values within the dataset that fell within the fences. Any values below a DL were not included, however the DLs and the number of samples above DL were indicated on the boxplots.

7.3.3.3 Testing Assumptions for Statistical Analysis

The assumptions of ANOVA and ANCOVA are that the residuals of the data, after being fit to the model, are normally distributed and have equal variance among groups. The assumption of normality was assessed using the Shapiro-Wilk test, while Levene's test was used to assess equality of variances. Significant differences in assumptions were evaluated using an α of 0.01 (i.e., *P*-values < 0.01 indicated assumptions were not met). If the assumptions of normality and equality of variance were not met, the data were $\log_{10}$-transformed and the assumptions were re-assessed. When the assumptions of ANOVA or ANCOVA could not be met using a $\log_{10}$ transformation, the nonparametric rank ANOVA or rank ANCOVA was used and post hoc pairwise comparisons were made using a Tukey's method for multiple comparisons on rank values.

In addition to the assumptions of normality and equality of variance, ANCOVA has the additional assumption that the parameter regression slopes are parallel among sampling areas or years. To test this assumption, the ANCOVA was conducted by first fitting separate regression models for each sampling area using a general linear model that included an interaction term between the categorical variable (i.e., sampling area or year) and covariate:

$$\textit{Full ANCOVA model:} \qquad y = \beta_0 + \beta_1(x) + \beta_2(category) + \beta_3(x) \times (category) + \varepsilon$$

where y is the response variable, x is the covariate, $category$ is the categorical indicator variable, and ε is the error term. If the coefficient β_3 of the $(x) \times (category)$ interaction term was not significant (i.e., $P > 0.01$), then the slopes were considered parallel and the ANCOVA proceeded by testing the significance of the coefficient β_2 of the $(category)$ term in the reduced ANCOVA model that fits separate regressions for each categorical group, but with a common regression slope:

$$\textit{Reduced ANCOVA model:} \qquad y = \beta_0 + \beta_1(x) + \beta_2(category) + \varepsilon$$

When a significant interaction was observed, the regression slopes were considered statistically significantly different. When the covariate was a strong predictor of the response variable, and the ANCOVA had a high coefficient of determination ($R^2 > 0.80$), the test for parallel slopes had high power to detect a difference that may not be practically significant. In this case, when the interaction term in the full ANCOVA model was significant, the slopes were fixed as parallel by fitting the reduced ANCOVA model (because the reduced model explained almost

as much [i.e., within 2%] of the variability in the response variable as the full model). In this case, the ANCOVA proceeded under the assumption that the regression slopes between groups were practically similar (Barrett et al. 2010). If slopes could not be considered practically parallel (difference in $R^2 > 0.02$), then endpoints were compared at the least and greatest overlapping covariate values (Section A1.7, Environment Canada 2012).

Statistical outliers were evaluated using studentized residuals (SR) from the ANOVA and ANCOVA models. A magnitude of 3.5 for the SR was used to identify unusual observations. When an outlier was detected, the validity of the value was examined. If the outlier was determined to be the result of data entry error, the error was corrected; if the outlier was not the result of data entry error and could not be resolved otherwise, the outlier was removed from the analysis and documented. All statistical comparisons were completed using R version 4.1.1 (R Core Team 2021).

7.3.3.4 Relative Percent Difference

The relative percent differences (RPDs) in effect endpoints between sampling years were calculated when significant differences in endpoints were observed, by expressing the difference as a percentage of the mean as follows:

$$Relative\ Percent\ Difference\ (RPD) = \frac{\left|\bar{x}_{Group1} - \bar{x}_{Group2}\right|}{\bar{x}_{(Group1+Group2)}} * 100$$

where $\bar{x}$ is the mean of the endpoint, and $Group_1$ and $Group_2$ refer to the years being compared. If the statistical comparison was conducted on log_{10}-transformed data, then the RPD was calculated using geometric means. For effect endpoints analyzed using rank ANOVA, RPDs were calculated using medians. For effect endpoints analyzed using ANCOVA, RPDs were calculated using least squares means.

To confirm that differences in tissue concentrations between years were real and less likely to be attributed to low concentrations of target constituents, analytical variability, and spatial and temporal variation, an RPD of 100% was used to differentiate the types of expected variability from those of potential biological importance (Environment Canada 2012).

7.3.3.5 Magnitude of Effect

The magnitude of effect for effect endpoints among sampling areas in 2023 were calculated when significant differences in endpoints or tissue concentrations were observed, by expressing the difference as a percentage of the reference mean as follows (Environment Canada 2012):

$$Magnitude\ of\ Effect = \frac{\bar{x}_{Milne} - \bar{x}_{Reference}}{\bar{x}_{Reference}} * 100$$

where $\bar{x}$ is the mean of the endpoint, and *Milne* and *Reference* refer to the Milne Port area and the appropriate Reference area, respectively. If the statistical comparison was conducted on log_{10}-transformed data, then the magnitude of effect was calculated using geometric means. For effect endpoints analyzed using rank ANOVA, the magnitude of effect was calculated using medians. For effect endpoints analyzed using ANCOVA, the magnitude of effect was calculated using least squares means.

For each finfish health endpoint, magnitudes of effect were compared with the critical effect size (CES) defined in the MDMER for that health endpoint. The CES for age, size-at-age, relative liver weight, and relative gonad weight is ±25% of the reference area mean; the CES for condition (relative weight) is ±10% of the reference area mean.

For finfish and shellfish tissue chemistry, a CES of 100% was used for tissue chemistry endpoints to differentiate random variability from those differences of potential biological importance (Environment Canada 2012). This approach was taken to validate that differences in concentrations of metals between years were real and less likely to be attributed to analytical variability, limitations of reporting (i.e., low concentrations of target contaminants), or spatial and temporal variation.

7.3.3.6 Power Analysis

Power analyses were performed to determine the minimum detectable difference of fish health and tissue chemistry endpoints. Target sample sizes for fish health endpoints were 20 Fourhorn Sculpin of each sex (40 total) and 40 *H. arctica*, and eight samples (24 total) for tissue chemistry for each fish species (i.e., Arctic Char, Fourhorn Sculpin, *H. arctica*). These sample sizes were used to estimate the sensitivity of future comparisons to detect differences by expressing the minimum detectable difference as a percent change relative to the mean. Type I (α) and Type II (β) error rates were set to 0.10 (Environment Canada 2012). Power analyses were conducted using the power and sample size function in G*Power 3.1 (Faul et al., 2007).

7.3.4 Guideline Comparison

Tissue concentrations of mercury and selenium for Arctic Char, Fourhorn Sculpin, and *H. arctica* sampled from 2018 to 2023 were compared to applicable tissue quality guidelines. Mercury concentrations were compared to Health Canada's Maximum Levels for Chemical Contaminants in Foods mercury consumption guideline of 0.5 mg/kg ww (Health Canada 2015). Selenium concentrations in Arctic Char and Fourhorn Sculpin were compared to the British Columbia Ministry of Environment (BC MOE) fish tissue guideline of 4 mg/kg dw (BC MOE 2014). Relevant guidelines were not available for other tissue chemistry parameters.

7.3.5 Quality Management

The field and laboratory quality assurance and quality control (QA/QC) procedures described in the following sections were implemented at each stage of the fish survey (i.e., field sampling, data entry, sample shipment, laboratory analyses, data analyses and report preparation) to produce technically sound and scientifically defensible results.

7.3.5.1 Field QA/QC

As part of practices for field operations for this program, the following QA/QC procedures were undertaken:

- Detailed specific work instructions outlining each field task were provided to the field personnel prior to the field programs.

- A pre-field meeting with the field crew and project team lead was conducted to review the specific work instructions so that procedures were understood.
- Samples were collected by experienced personnel and were labelled, preserved, and shipped according to laboratory instructions described in Golder TP 8.1-3, Fish Inventory Methods (unpublished information) and Golder TP 8.16-0, Fish Health Assessment – Metals (unpublished information).
- Fish identification was recorded to species, where possible, with identifications verified using fish field guides.
- Field equipment (e.g., electronic scales and water quality meters) were regularly calibrated according to manufacturer's recommendations.
- Detailed field notes were recorded in pencil in waterproof field notebooks, on waterproof pre-printed field data sheets, or directly entered electronically into an excel spreadsheet.
- Field data (i.e., data sheets, notebooks, and electronic spreadsheets) were checked at the end of each day for completeness and accuracy.

Samples were documented and tracked using chain of custody (COC) forms and receipt of samples by the analytical laboratory was confirmed. Field crews were responsible for managing sample shipment to the analytical laboratories. Prior to sample shipment, field crews confirmed the following:

- Required samples were collected and accounted for.
- COC and analytical request forms were completed and correct.
- Proper sample labelling and documentation procedures were followed.

7.3.5.2 Data Analysis QA/QC

Field-collected data, data sheets, and field notebooks were reviewed for completeness and unexpected values or trends. At minimum, 10% of the field data entered electronically were verified by a second person to identify transcription errors. If any errors were identified, a 100% quality check was implemented. Results of statistical data analyses were reviewed by an independent biologist experienced in statistical analysis. Tables containing data summaries and statistical results were reviewed and values were verified by a second, independent individual.

7.3.5.2.1 Tissue Chemistry

The fish tissue chemistry dataset was visually assessed for outliers using scatterplots, and erroneous values were corrected, if possible (i.e., if values were identified as data entry errors). Statistical analyses and data summary tables were independently reviewed and verified by a second individual experienced in statistical analysis. Internal laboratory QA/QC at BV Labs included analysis of duplicates to evaluate the variance in the measurement, matrix spikes to evaluate sample matrix interference, method blanks to identify laboratory contamination, reagent blanks to determine any analytical contamination, spiked samples to evaluate method accuracy, surrogates to evaluate extraction efficiency, and QC standards used as an independent check of method accuracy. Upon receipt of the tissue chemistry data from BV Labs, standard checks were performed to screen for potential data quality issues by:

- confirming that each requested variable was analyzed
- reviewing the reported units
- reviewing any hold time exceedances
- reviewing internal laboratory QA/QC results

Most results met the laboratory quality acceptance criteria for representativeness (e.g., no detected concentrations in procedural blanks) and accuracy (e.g., spiked blanks, containing a known amount of analyte, within acceptable range). Lab duplicate control limits for several parameters were the exception, as RPD limits were exceeded as follows:

- Lead and silver control limits for Arctic Char were exceeded by 73% and 72%, respectively. Other quality control parameters were met, and data were considered acceptable.
- Lead concentration in the method blank for *H. arctica* was above the DL (value = 0.0020; DL = 0.0013 mg/kg ww). Lead concentrations in *H. arctica* samples were more than 10 times greater than in the method blank and, therefore, the method blank contamination was considered irrelevant. Other QC parameters were met.

Visual assessment of tissue chemistry data identified three reported metals concentrations in *H. arctica* samples which were possibly erroneous. Two composite samples from Milne Port (MLN-HTAR-COMP-METALS-5, MLN-HTAR-COMP-METALS-8) and one composite sample from Tugaat River Estuary (REF-HTAR-COMP-METALS-2) were reanalyzed twice by the laboratory: MLN-HTAR-COMP-METALS-5 for lead, and MLN-HTAR-COMP-METALS-8 and REF-HTAR-COMP-METALS-2 for silver. Results of laboratory re-analysis indicated initial concentrations were at least one order of magnitude greater than the concentrations determined through re-analysis, and variability in reported concentrations was attributed to sample heterogeneity (personal communication, N. Amer, BV Labs, 23 January 2024).

Metal concentrations for these samples determined during re-analysis were chosen for inclusion in the MEEMP tissue chemistry dataset. Final concentrations were estimated using the geometric mean of the two concentrations reported during re-analysis. Certificate of analysis forms, including those from sample re-analysis, are provided in Appendix 7E. Overall, the fish tissue chemistry data were considered reliable and representative of site conditions at the time of sampling.

7.3.6 TARP Assessment

As part of applying the Trigger Action Response Plan (TARP; Baffinland 2024), fish health and tissue chemistry performance indicators were screened against condition status/thresholds in 2023, in order to assess risk levels for each performance indicator. The following performance indicators and condition status/threshold values were used when evaluating fish health and tissue chemistry (Table 7-5).

Table 7-5: Marine Environment TARP Framework for Fish Health and Tissue Chemistry (Baffinland 2024)

Component	Performance Indicators[3]	Condition Status/Threshold		
		Low Risk	Moderate Risk	High Risk
Fish Health	Fourhorn Sculpin ■ Age ■ Size-at-age (i.e., total weight at age) ■ Condition as relative weight (i.e., total weight at total length) ■ Relative liver weight (i.e., liver weight at total weight) ■ Relative gonad weight (i.e., gonad weight at total weight) *Hiatella arctica* ■ Length-frequency analysis ■ Whole animal wet weight ■ Condition as relative weight (i.e., whole animal wet weight at total length) ■ Relative shell weight (i.e., dry shell weight at total length) ■ Relative gonad weight (i.e., gonad weight at whole animal wet weight)	A statistically significant difference ($P < 0.1$) in effect indicators[8] relative to the reference area and change is in direction that indicates an impairment to fish health and is of magnitude greater than or equal to a defined critical effect size (CES)[4] for that effect indicator.	Confirmed[5] Low Risk Status/ Threshold and mean/median[6] for the same effect indicator is beyond the baseline (FEIS) normal range[7] (if available) or regional normal range[8] AND Is supported by consistent effects in one or more other study components (i.e., water quality, sediment quality and benthic invertebrates) which links the results to the Project.	To be determined based on outcome of moderate response investigations.

[3] The following endpoints were included or excluded relative to the proposed TARP framework in order to better align the Fish Health and Tissue Chemistry monitoring program with the MDMER EEM program: Fourhorn Sculpin – age (included), length-frequency analysis (excluded).

[4] Definition of a magnitude of change that is indicative of impairment to fish health is based on the critical effect sizes defined by Environment Canada's Metal Mining Effluent Regulations Guidance Document (Environment Canada 2012) and refers to an increase or a decrease in fish health endpoints. Additional critical effect sizes may be defined in the future (i.e., beyond those defined by ECCC).

[5] Confirmed indicates that the Risk Status/ Threshold trigger has been observed in at least two consecutive monitoring programs, whether during the regular monitoring schedule or confirmed through a special study. For fish, the two or more endpoints that triggered the Moderate Risk Status/ Threshold may be in one species (i.e., two endpoints in one species) or two species (i.e., one endpoint in one species, as second endpoint in another species).

[6] The use of the mean or median will depend on the normality of the dataset used to calculate the normal range for each endpoint or tissue chemistry parameter (i.e., if raw or transformed data do not meet the assumptions of normality, the median will be used to provide an estimate of central tendency instead of the mean).

[7] Baseline (FEIS) normal range is based on the FEIS dataset, including operational monitoring data from Milne Inlet and Steensby Inlet, and includes fish length, weight and condition (K).

[8] Regional normal range will be calculated using all available reference area data (i.e., will include annual and ongoing reference area data as it becomes available).

Component	Performance Indicators[3]	Condition Status/Threshold		
		Low Risk	Moderate Risk	High Risk
Fish Tissue Chemistry	Primary constituents of Project iron ore: ▪ Aluminum ▪ Magnesium ▪ Iron Metals with the potential to bioaccumulation and biomagnify in the food web: ▪ Mercury ▪ Selenium	A statistically significant difference ($P < 0.1$) in one or more metals concentrations in a sentinel species relative to the reference area, and change is in the direction[9] that indicates impairment to fish health and is of magnitude[10] greater than or equal to the defined CES.	A confirmed[11] Low Risk Status/ Threshold for one or more metals that is also outside the regional normal range[12], and is supported by consistent effects in one or more other study components (i.e., water quality, sediment quality and benthic invertebrates) which links the results to the Project. OR The mean mercury or selenium concentrations (or ≥50% of the individual samples) in Arctic Char tissue chemistry samples are beyond the respective CFIA[13] or BCMOE[14] guidelines.	To be determined based on outcome of moderate response investigations.

CES = critical effect size; FEIS = Final Environmental Impact Statement; CFIA = Canadian Food Inspection Agency; BC MOE = British Columbia Ministry of Environment.

[9] For tissue chemistry, only an increase in concentration will be considered indicative of a toxicological response.

[10] For fish tissue chemistry parameters, the critical effect size is a difference of 100%.

[11] Confirmed indicates that the Action Status/Threshold trigger has been observed in at least two consecutive monitoring programs, whether during the regular monitoring schedule or confirmed through a special study.

[12] Regional normal range is anticipated to include Arctic Char tissue chemistry data from the FEIS (i.e., Milne Inlet and Steensby Inlet) as well as ongoing reference area tissue chemistry data (for *Hiatella arctica* and Fourhorn Sculpin).

[13] Value is 0.5 mg/kg ww total mercury per CFIA (2014) Canadian Food Inspection Agency Fish Products Standards and Methods Manual: Appendix 3 Canadian Guidelines for Chemical Contaminants and Toxins in Fish and Fish Products. Ottawa, ON.

[14] Protection of aquatic life chronic criteria for fish tissue selenium concentrations are 15.1 mg/kg dw for ovary, 8.5 mg/kg dw for whole body, or 11.3 mg/kg dw for skinless, boneless muscle fillet per USEPA (2016) Technical Support for Fish Tissue Monitoring for Implementation of EPA's 2016 Selenium Criterion Draft, EPA 820-F-16-007, United States Environmental Protection Agency, Office of Water.

7.4 Results

In 2023, fish health data were collected for Arctic Char, Fourhorn Sculpin, and *H. arctica*, and tissue chemistry samples were submitted for analysis of metals and PAHs from all three species. Fish health data collected in 2023 are provided in Appendix 7B, Tables 7B-1 to 7B-3, and summaries of Fourhorn Sculpin and *H. arctica* fish health data collected in previous monitoring years are presented in Appendix 7B, Tables 7B-4 to 7B-5. Tissue chemistry data collected in 2023 are provided in Appendix 7C, Tables 7C-3 to 7C-8 and summaries of tissue chemistry data collected in previous monitoring years are presented in Appendix 7C, Tables 7C-9 to 7C-11. Fish health and tissue chemistry data collected in previous sampling years are also provided in past MEEMP Reports (e.g., Golder 2019, 2020b, 2021; WSP 2023).

7.4.1 Fish Health

7.4.1.1 Arctic Char

A total of 22 incidental mortalities of Arctic Char from Milne Inlet were processed in 2023 as part the fish community assessment (Chapter 6.0), including 14 adults (five females, nine males) and eight juveniles. Processed Arctic Char ranged in age from 4 to 25 years, in total length from 313 to 647 mm, and in weight from 320 to 2,014 g. Condition factor ranged from 0.53 to 1.24. Fish were considered to be in good health, with many being described as having abundant internal fat and few being observed with parasite infections.

7.4.1.1.1 Survival - Age

Ages of incidental mortalities of Arctic Char were comparable between 2021, 2022, and 2023 (Figure 7-1). Ages ranged from 4 to 17 years in 2021, 4 to 22 years in 2022, and 4 to 25 years in 2023, with maximum ages reported in 2022 and 2023 belonging to fish that were more than five years older than others sampled in their respective years. The median age in 2022 (11.5 years) was greater than that in 2021 or 2023 (8.5 and 9.0 years, respectively (Figure 7-1).

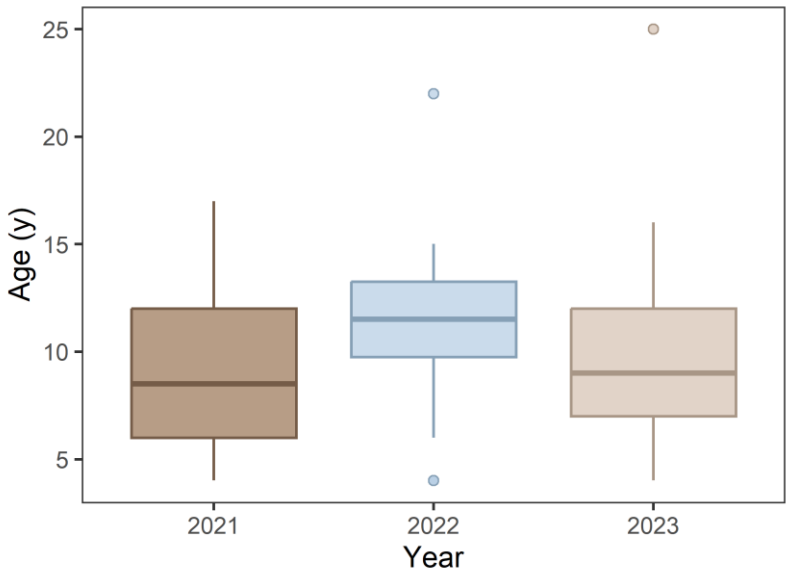

Figure 7-1: Boxplots of Ages of Arctic Char Incidental Mortalities Sampled from Milne Inlet, 2021 to 2023

7.4.1.1.2 Stomach Contents

A total of 21 stomachs collected from incidental mortalities of Arctic Char were analyzed for stomach contents (Figure 7-2). A total of 17 unique prey items were identified: 11 amphipods, three calanoid copepods, two fish, two snails, two mysids, one polychaete worm, one dipteran fly, one additional copepod, and one additional crustacean. Dominant prey items consumed by Arctic Char in 2023 included crustaceans (56% by weight), and fish (43% by weight). Crustaceans were comprised of amphipods (24% by weight), calanoid copepods (6.3% by weight), mysids (10% by weight), and unidentified crustaceans (16% by weight). Fish were comprised of sand lance species (*Ammodytes* spp.; 42% by weight) and unidentified fishes (1.1% by weight). Larval stage cestode tapeworm parasites (i.e., plerocercoids) were identified from the stomach of one Arctic Char.

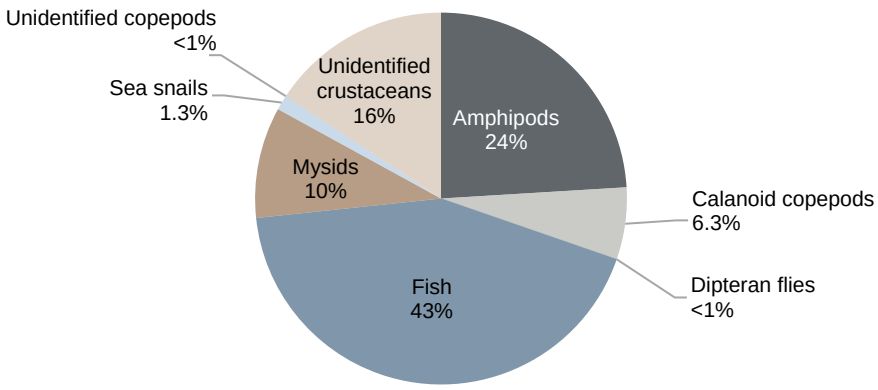

Figure 7-2: Relative Stomach Contents by Weight from Arctic Char Incidental Mortalities Sampled from Milne Inlet, 2023

7.4.1.1.3 Temporal Comparisons

7.4.1.1.3.1 Condition Factor

Condition factor of Arctic Char was compared between 2021, 2022, and 2023 (Table 7-6; Figure 7-3) and data for all sexes and life stages were combined as described in Section 7.3.4.1. Condition factor ranged from 0.75 to 1.22 in 2021, from 0.76 to 1.33 in 2022, and 0.53 to 1.24 in 2023 (Table 7-6). Mean condition differed significantly among sampling years ($F_{2,71}$ = 4.56, P = 0.013). *Post-hoc* pairwise comparisons indicated condition factor was significantly lower in 2023 compared to 2022 (P = 0.010; RPD: 11.9%) but did not differ significantly among other sampling years (P > 0.10).

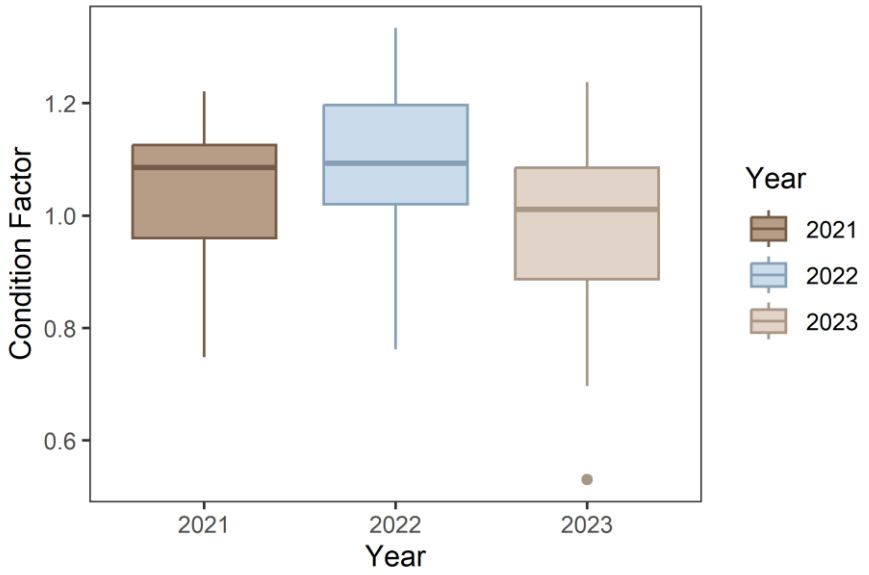

Figure 7-3: Boxplots of Condition Factor for Arctic Char Captured throughout Milne Inlet, 2021 to 2023

Age (y)	21	4	25	9.0	10.0	4.8	1.0

n = sample size; Min = minimum; Max = maximum; SD = standard deviation; SE = standard error.

(a) Fork length measurements were not collected in 2021 or 2023.

(b) Total length measurements were not collected in 2022.

7.4.1.2 Fourhorn Sculpin

A total of 40 Fourhorn Sculpin were processed from the Milne Port area during the 2023 fish health assessment, including 20 females and 20 males. A total of 25 Fourhorn Sculpin were processed from the Koluktoo Bay reference area, including 18 females and seven males. Summary statistics for processed fish are provided in Table 7-7.

Length-frequency distributions for Fourhorn Sculpin from Milne Port were right-skewed (i.e., longer right tail in the frequency distribution) for both female and male fish (Figure 7-4), indicating a strong presence of larger size classes in the population. At the time of sampling, female Fourhorn Sculpin were longer (RPD 13%) and heavier (RPD 37%), based on median total length and total weight, respectively, than male Fourhorn Sculpin, and had greater energy stores, based on comparisons of median LSI (RPD 29%). Both sexes had median ages of approximately 6, with females ranging from 5 to 9 years and males ranging from 4 to 8 years. Female Fourhorn Sculpin ranged in length from 218 mm to 323 mm and in weight from 105 g to 329 g. Female condition factor ranged from 0.85 to 1.42, LSI ranged from 2.88 to 6.72, and GSI ranged from 2.24 to 6.77. Male Fourhorn Sculpin ranged in length from 203 mm to 281 mm and in weight from 76.4 g to 249 g. Male condition factor ranged from 0.83 to 1.70, LSI ranged from 1.60 to 9.25, and GSI ranged from 1.61 to 9.53. No difference in condition (as relative weight) was observed between female and male Fourhorn Sculpin from the Milne Port area (P = 0.494; Figure 7-5).

Length-frequency distributions for Fourhorn Sculpin from Koluktoo Bay were roughly symmetric for both female and male fish, suggesting two age-classes were present among captured fish (Figure 7-4). At the time of sampling, female and male Fourhorn Sculpin from Koluktoo Bay were roughly the same size, based on median total length and total weight, but female fish showed slightly greater energy stores, based on comparisons of median LSI (RPD 6%). Both sexes had median ages of approximately 7, with females ranging from 4 to 9 years and males ranging from 6 to 9 years. Female Fourhorn Sculpin ranged in length from 185 to 265 mm and in weight from 50.1 to 169 g. Female condition factor ranged from 0.74 to 1.17, LSI ranged from 2.71 to 6.20, and GSI ranged from 2.51 to 7.87. Male condition factor ranged from 0.91 to 1.12, LSI ranged from 2.33 to 5.66, and GSI ranged from 1.90 to 4.79. No difference in condition (as relative weight) was observed between female and male Fourhorn Sculpin from Koluktoo Bay (P = 0.447; Figure 7-5).

7.4.1.2.1 Spatial Comparisons

7.4.1.2.1.1 Survival – Age

Ages of Fourhorn Sculpin were compared between Milne Port and Koluktoo Bay reference area (Table 7-10). Female ages ranged from 5 to 9 years in the Milne Port area and from 4 to 9 years in the Koluktoo Bay reference area, while male ages ranged from 4 to 8 years in the Milne Port Area and from 6 to 9 years in the Koluktoo Bay reference area (Table 7-7; Figure 7-6). Mean ages for female Fourhorn Sculpin did not differ significantly between sampling areas, whereas for male Fourhorn Sculpin, mean age was significantly greater in the Koluktoo Bay reference area compared with Milne Port (Table 7-10). The magnitude of effect of the difference in male Fourhorn Sculpin age (-20%) was less than the CES (±25%).

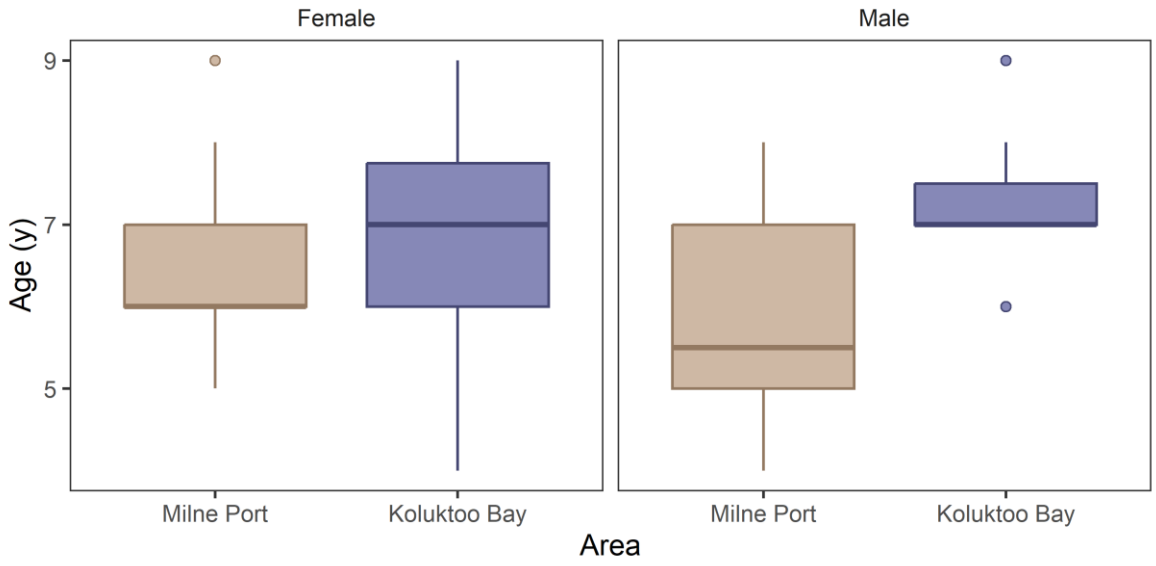

Figure 7-6: Boxplots of Ages of Female and Male Fourhorn Sculpin Sampled from the Milne Port Area and Koluktoo Bay Reference Area, 2023

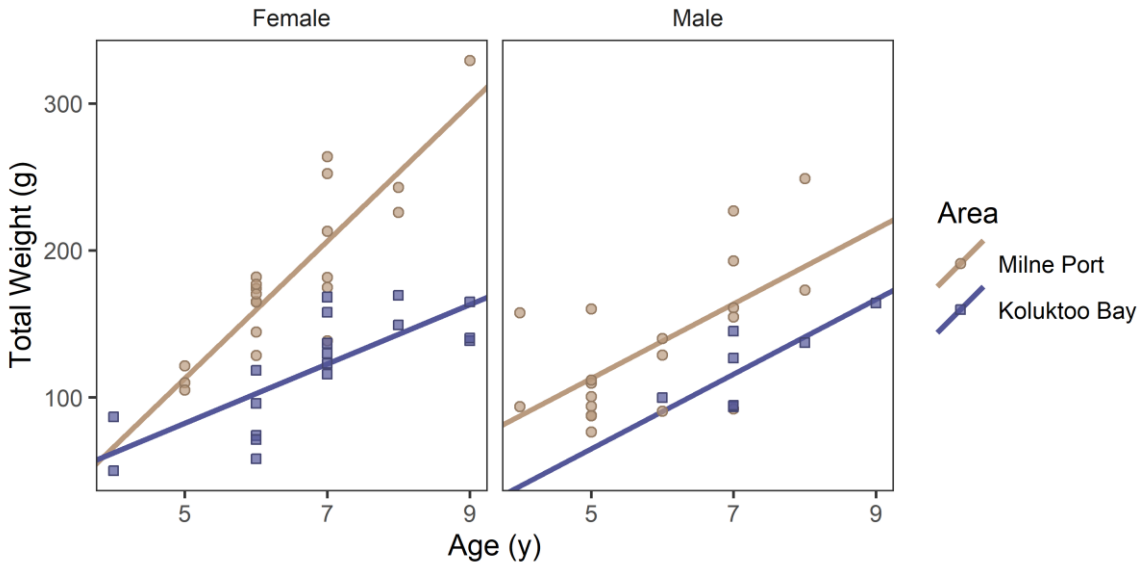
7.4.1.2.1.2 Growth – Size-at-Age

Size-at-age was compared between Milne Port and Koluktoo Bay using total weight-at-age (Figure 7-7). For female Fourhorn Sculpin, a significant interaction term (P = 0.001) indicated that relationships between age and total weight differed between Milne Port and Koluktoo Bay (Figure 7-8): therefore, size-at-age was compared at the youngest and oldest overlapping ages between the sampling areas. For both younger and older female Fourhorn Sculpin (i.e., age 5 and 9 years, respectively), mean size-at-age was significantly greater at Milne Port compared to Koluktoo Bay, with magnitudes of effect exceeding the CES and corresponding to 37% and 84%, respectively, greater size-at-age at Milne Port. For male Fourhorn Sculpin, size-at-age was greater in the Milne Port Area than the Koluktoo Bay reference area, with a magnitude of effect exceeding the CES (i.e., 50%; Table 7-10). However, the direction of the observed effects (i.e., higher in Milne Port) did not indicate an impairment to the health of female or male Fourhorn Sculpin.



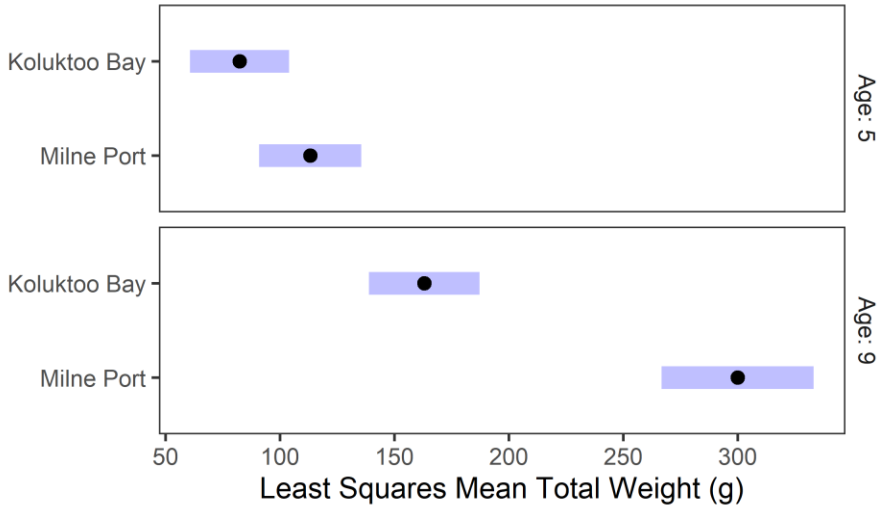


Figure 7-7: Size-at-Age Relationships for Female and Male Fourhorn Sculpin Sampled from the Milne Port Area and Koluktoo Bay Reference Area, 2023

Blue bars represent 90% confidence intervals. See Table 7-10 for statistical model information.

Figure 7-8: Least Squares Mean Total Weight-at-Age of Female Fourhorn Sculpin Captured from the Milne Port Area and Koluktoo Bay Reference Area, 2023

7.4.1.2.1.3 Condition – Relative Weight and Relative Liver Weight

Condition of Fourhorn Sculpin was compared between Milne Port and Koluktoo Bay using relative weight (as weight-at-length) and relative liver weight (as liver weight-at-total weight). Relative weight differed significantly between areas for female Fourhorn Sculpin, but did not differ significantly between areas for male Fourhorn Sculpin (Table 7-10; Figure 7-9). For female Fourhorn Sculpin, relative weight was significantly greater in the Milne Port area relative to the Koluktoo Bay reference area: the magnitude of difference (10%) was equal to the CES (±10%). For females, condition factor ranged from 0.85 to 1.42 in Milne Port, and 0.74 to 1.17 in Koluktoo Bay; for males, condition factor ranged from 0.83 to 1.70 in Milne Port, and 0.91 to 1.12 in Koluktoo Bay (Table 7-7).

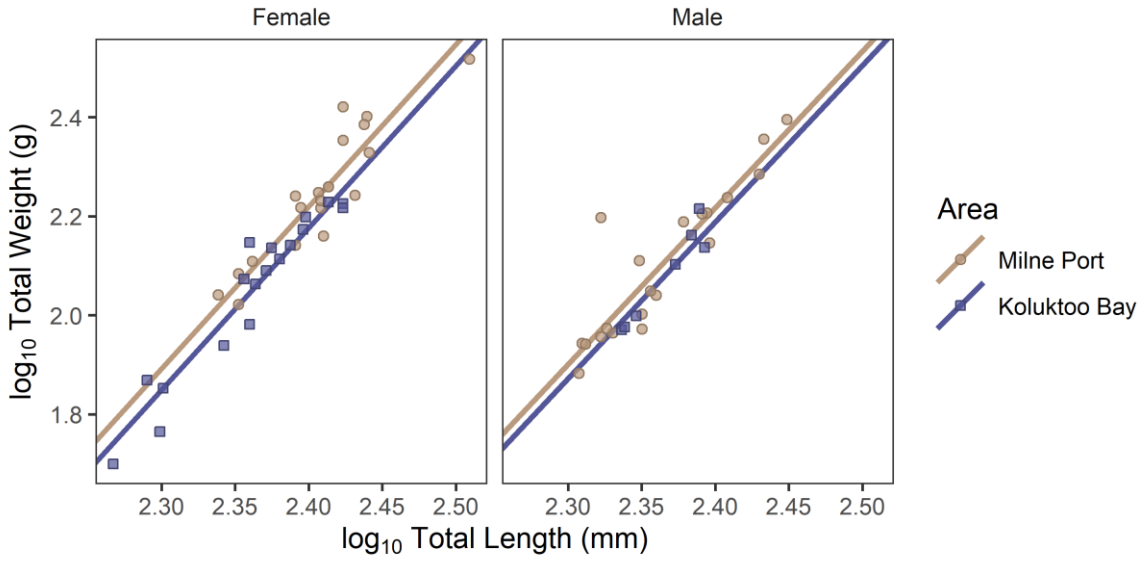

Figure 7-9: Weight-at-Length Relationships for Female and Male Fourhorn Sculpin Sampled from the Milne Port Area and Koluktoo Bay Reference Area, 2023

Similarly to condition (i.e., relative weight), relative liver weight differed significantly between areas for female Fourhorn Sculpin but not for male Fourhorn Sculpin (Table 7-10; Figure 7-10). For female Fourhorn Sculpin, relative liver weight was significantly greater in the Koluktoo Bay reference area relative to the Milne Port area: the magnitude of effect (-17%) was less than the CES (±25%; Table 7-10). The LSI for female Fourhorn Sculpin ranged from 2.88 to 6.72 in the Milne Port area and from 2.71 to 6.20 in Koluktoo Bay reference area; male LSI ranged from 2.09 to 5.64 in Milne Port and 2.33 to 5.66 in Koluktoo Bay (Table 7-7).

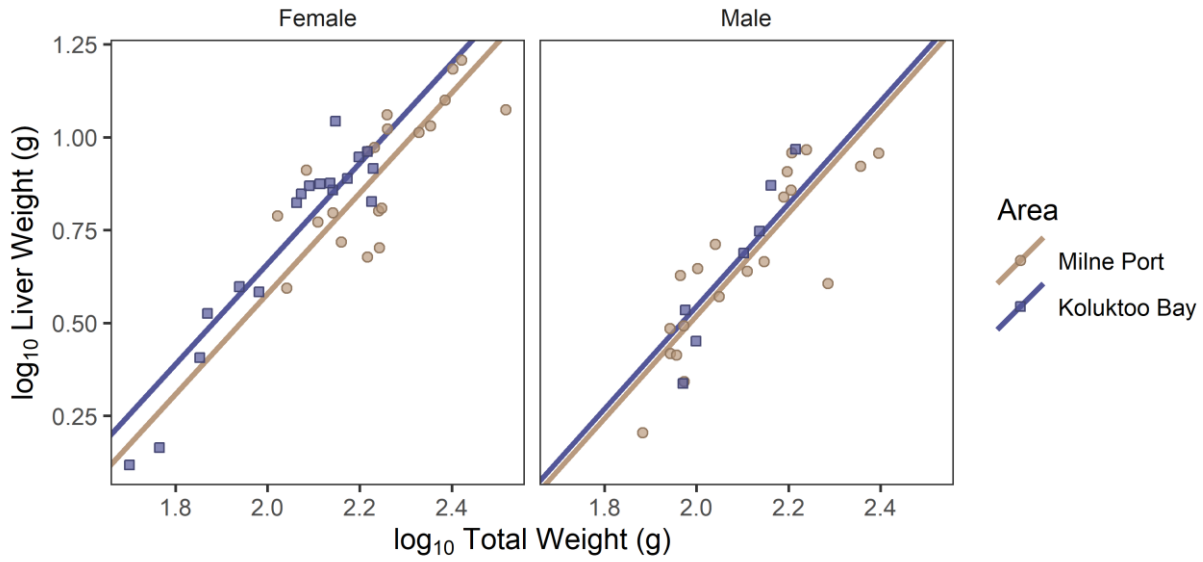

Figure 7-10: Relative Liver Weight for Female and Male Fourhorn Sculpin Sampled from the Milne Port Area and Koluktoo Bay Reference Area, 2023

7.4.1.2.1.4 Reproduction – Relative Gonad Weight

Relative gonad weights were compared between Milne Port and Koluktoo Bay using relationships between gonad weight and total weight in female and male Fourhorn Sculpin (Figure 7-11). Relative gonad weight differed significantly among sampling areas for female Fourhorn Sculpin, but did not differ significantly for male Fourhorn Sculpin (Table 7-10). For female Fourhorn Sculpin, relative gonad weight was significantly greater in fish from the Koluktoo Bay reference area compared to the Milne Port area: the magnitude of effect (-31%) was greater than the CES (±25%; Table 7-10). For females, GSI ranged from 2.24 to 6.77 in Milne Port, and 2.51 to 7.87 in Koluktoo Bay; for males, GSI ranged from 1.44 to 5.76 in Milne Port, and 1.90 to 4.79 in Koluktoo Bay (Table 7-7).

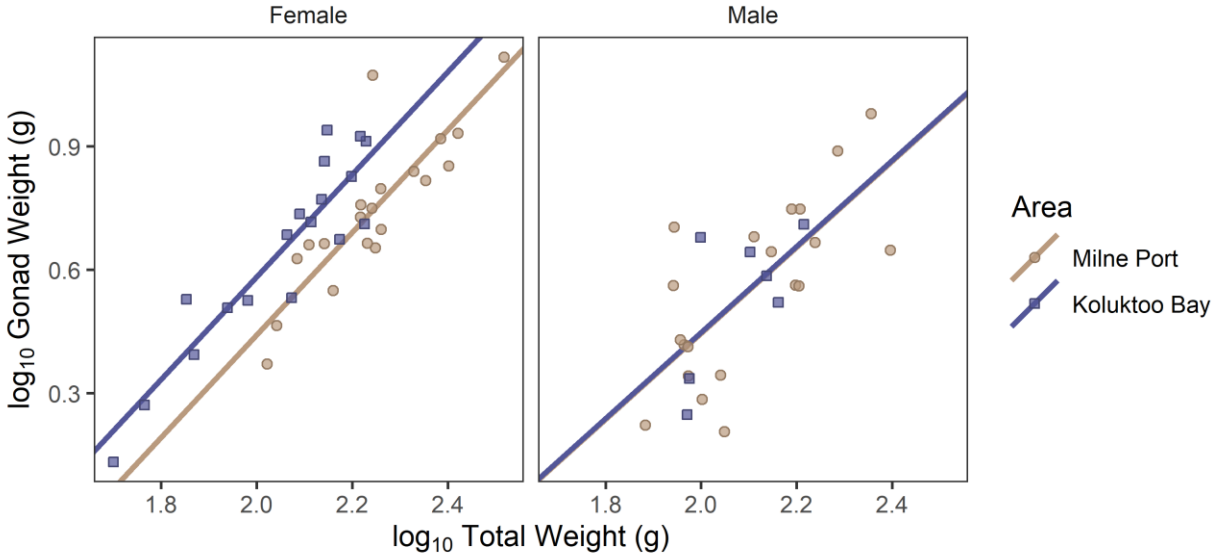

Figure 7-11: Relative Gonad Weight for Female and Male Fourhorn Sculpin Sampled from the Milne Port Area and Koluktoo Bay Reference Area, 2023

7.4.1.2.1.5 Stomach Contents

A total of 30 stomachs collected from Fourhorn Sculpin were analyzed for stomach contents: 16 from fish captured in the Milne Port area and 14 from fish captured in the Koluktoo Bay reference area. Stomach fullness ranged from 0% to 100%: stomachs were fuller on average in Milne Port (65% by volume) compared to the reference area (27% by volume). Three stomachs from Fourhorn Sculpin collected from Koluktoo Bay and one stomach from a Fourhorn Sculpin collected in the Milne Port area were empty.

Relative stomach contents differed among sampling areas (Figure 7-12) reflecting variability in diets. In the Milne Port area, the dominant prey item for Fourhorn Sculpin were fishes (88% by weight), mainly comprising sand lance species (*Ammodytes* spp.). Minor prey items included amphipods (6.2% by weight), unidentified crustaceans (3.5% by weight), mysids (also known as opossum shrimps; 1.1% by weight), pectinariid worms (trumpet worms of the family Pectinariidae; 1.0% by weight), and calanoid copepods as well as sea snails of the suborder Heterobranchia (<1%, respectively). In contrast, in the Koluktoo Bay reference area, dominant prey items for Fourhorn Sculpin included amphipods (47% by weight) and unidentified crustaceans (33% by weight). Minor prey items included sea snails (19% by weight) and calanoid copepods (1.0% by weight). Differences in stomach contents likely reflect differences in habitat and prey availability between the Milne Port and Koluktoo Bay. Site characterization surveys indicated a predominance of boulder habitat around Milne Port, whereas habitats in Koluktoo Bay were more variable, including boulders, cobble reefs, and sand bars. These habitat differences likely result in differences in prey items abundance and availability, thus driving differences in stomach contents of Fourhorn Sculpin among sampling areas.

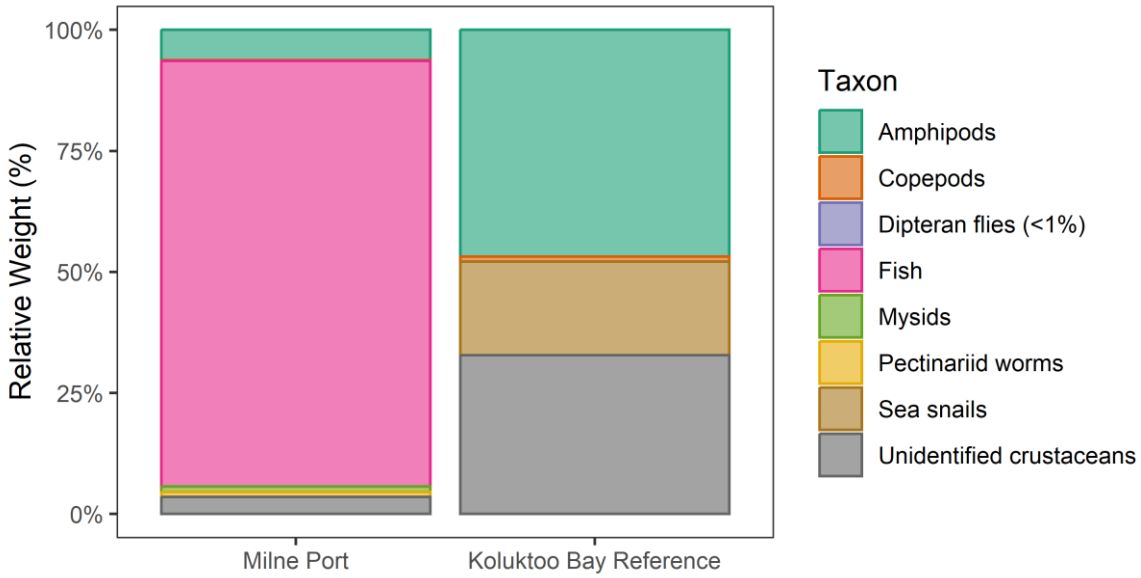

Figure 7-12: Relative Stomach Contents by Weight from Fourhorn Sculpin Sampled from Milne Port and Koluktoo Bay Reference Area, 2023

Table 7-8: Results of Statistical Comparisons Between Milne Port Area and Koluktoo Bay Reference Area for Fourhorn Sculpin, 2023

Notes: Statistically significant values and magnitudes of effect exceeding the CES are indicated in **bold**. Supporting information for statistical model results are provided in Appendix 7B, Table 7B-8. Statistical outliers are provided in Appendix 7B, Table 7B-10.

(a) For model components, please see Table 7-3.

(b) The magnitude of effect is calculated as the difference in least squares mean values between Milne Port and Koluktoo Bay: (Milne - Koluktoo) / Koluktoo × 100% (Environment Canada 2012).

(c) Critical Effect Size (CES) expressed as a percentage of the Koluktoo Bay mean.

(d) Power Analysis values presented on measurement scale. Log_{10}-transformed models include values for differences below and above the Koluktoo Bay mean.

(e) Minimum detectable difference expressed as unit difference from the Koluktoo Bay mean.

(f) Sensitivity is the minimum detectable difference expressed as a percent change in the Koluktoo Bay mean.

(g) The R^2 value for the full model was less than the threshold (0.791 < 0.800) for assuming slopes are practically parallel (Barrett et al., 2010). Therefore, size-at-age was compared at the smallest and largest overlapping covariate values among study years, following Section A1.7 in Environment Canada.

n = number; y = year; P-value = probability value; log_{10} = log_{10}-transformed data; rank = rank-transformed data; ANOVA = analysis of variance; ANCOVA = analysis of covariance; n/a = not applicable.

7.4.1.2.1.6 Abnormalities

Few abnormalities were observed in Fourhorn Sculpin sampled from the Milne Port area or the Koluktoo Bay reference area (Table 7-9). No external abnormalities were observed; however, several fish had parasitic cysts embedded in their fins or skin. Internal abnormalities primarily consisted of variation in liver colour, with light or pale livers observed for nine females and 14 males from Milne Port and three females and one male from Koluktoo Bay. Liver colour is closely tied to the level of blood perfusion (i.e., fresh circulating blood), and, therefore, the time elapsed between sacrifice and observation will influence the liver colour endpoint. Further, colour is subject to observer bias and is considered a less reliable indicator as a result. Internal parasites observed in Fourhorn Sculpin consisted of cysts embedded within the body cavity (i.e., on the stomach and digestive organs) which were present in 11 females and nine males from Milne Port and 13 females and five males from Koluktoo Bay. A parasitic worm was observed inside the body cavity of one male fish from Milne Port, and a parasitic roundworm was observed inside one female fish from Koluktoo Bay.

Table 7-9: Number and Description of External and Internal Abnormalities Observed in Fourhorn Sculpin Sampled from the Milne Port Area, 2023

Parameter	Milne Port		Koluktoo Bay		Description
	Female (n = 20)	Male (n = 18)	Female (n = 20)	Male (n = 7)	
External					
Body Deformity	0	0	0	0	-
Eyes	0	0	0	0	-
Skin	0	0	0	0	-
Thymus	0	0	0	0	-
Opercula	0	0	0	0	-
Gills	0	0	0	0	-
Pseudobranchs	0	0	0	0	-
Fins	0	0	0	0	-
Vent	0	0	0	0	-
Parasitization	3	2	4	1	Cysts embedded in fins, skin
Internal					
Liver	9	14	3	1	Pale coloration or general discolouration[(a)]
Spleen	0	0	0	0	-
Gall bladder	0	0	0	0	-
Gonad	0	0	0	0	-
Kidney	0	0	0	0	-
Parasitization	11	9	13	5	Cysts on internal organs, worm observed in body cavity

(a) Pale liver colouration/general discolouration is typically associated with a lack of perfusion following sacrifice and cessation of the heart beating; pale or discoloured livers were noted and documented but are not considered further.

- = no comments

7.4.1.2.2 Temporal Comparisons

7.4.1.2.2.1 Survival – Age

Ages of female and male Fourhorn Sculpin were compared between 2020, 2021, 2022, and 2023 (Table 7-7; Figure 7-13). Mean ages for female Fourhorn Sculpin increased significantly between 2020 and 2022, increasing by an average of one-year each sampling year, but remained consistent among other years (Table 7-10). Female ages ranged from 4 to 8 years in 2020, from 3 to 10 years in 2021, from 5 to 9 years in 2022, and from 5 to 9 years in 2023. For male Fourhorn Sculpin, mean ages also increased significantly between 2020 and 2022, similarly to female Fourhorn Sculpin, but remained consistent among other years (Table 7-10). Male ages ranged from 4 to 9 years in 2020, from 3 to 12 years in 2021, from 5 to 10 in 2022, and from 4 to 8 in 2023.

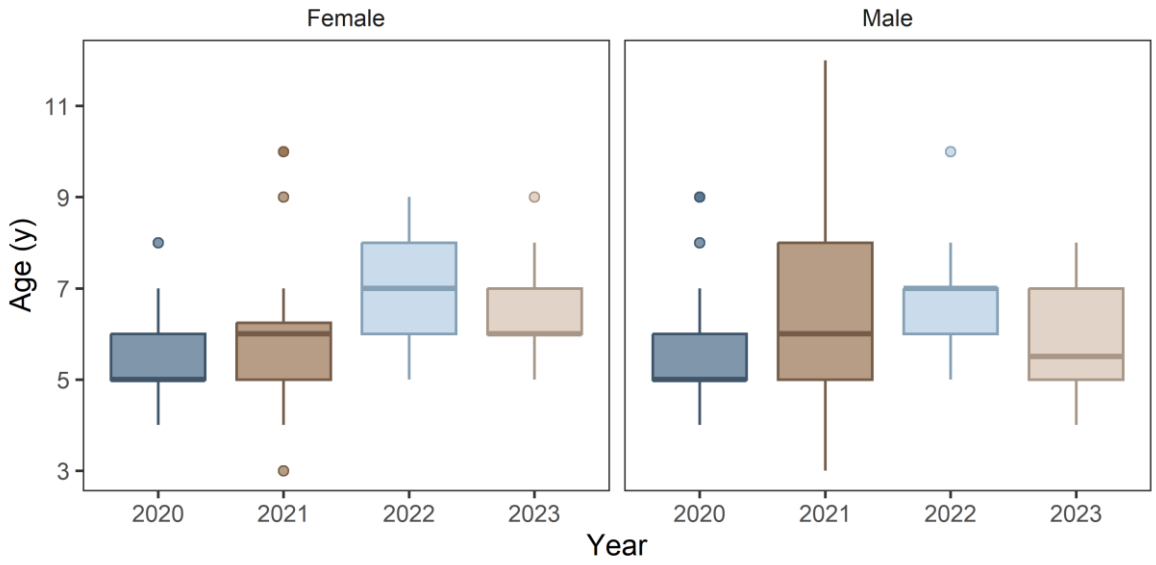

Figure 7-13: Boxplots of Ages of Female and Male Fourhorn Sculpin Sampled from the Milne Port Area, 2020 to 2023

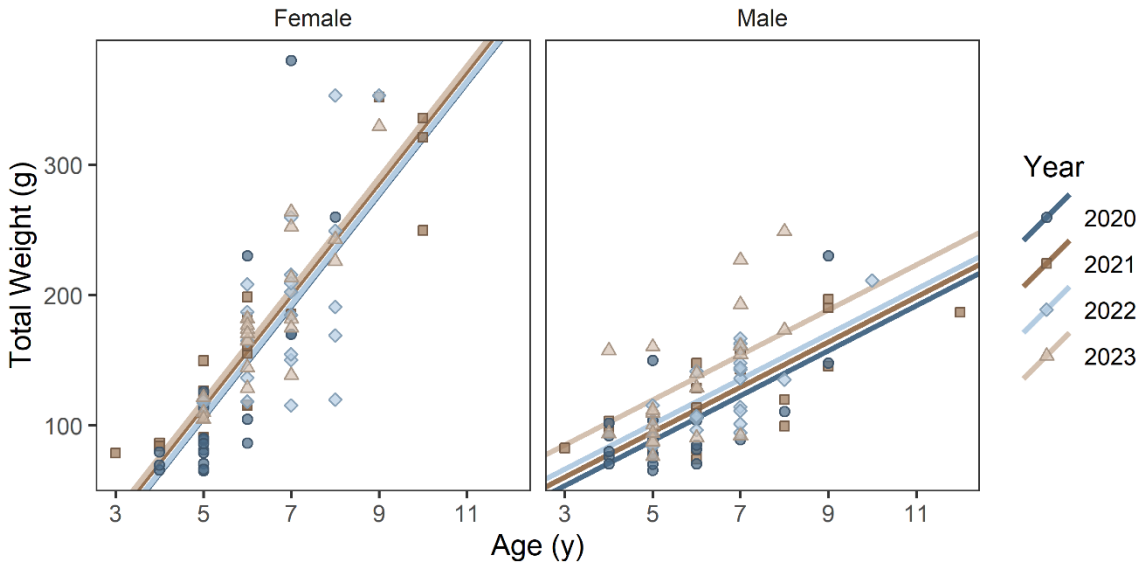
7.4.1.2.2.2 Growth – Size-at-Age

Size-at-age was compared between 2020, 2021, 2022, and 2023 using total weight-at-age (Figure 7-14). For female Fourhorn Sculpin, mean size-at-age did not differ among sampling years ($p = 0.256$; Table 7-10). For male Fourhorn Sculpin, size-at age was significantly greater in 2023 compared to 2020 and 2021, differing by 25% and 19% respectively (Table 7-10). No other pairwise differences were observed.



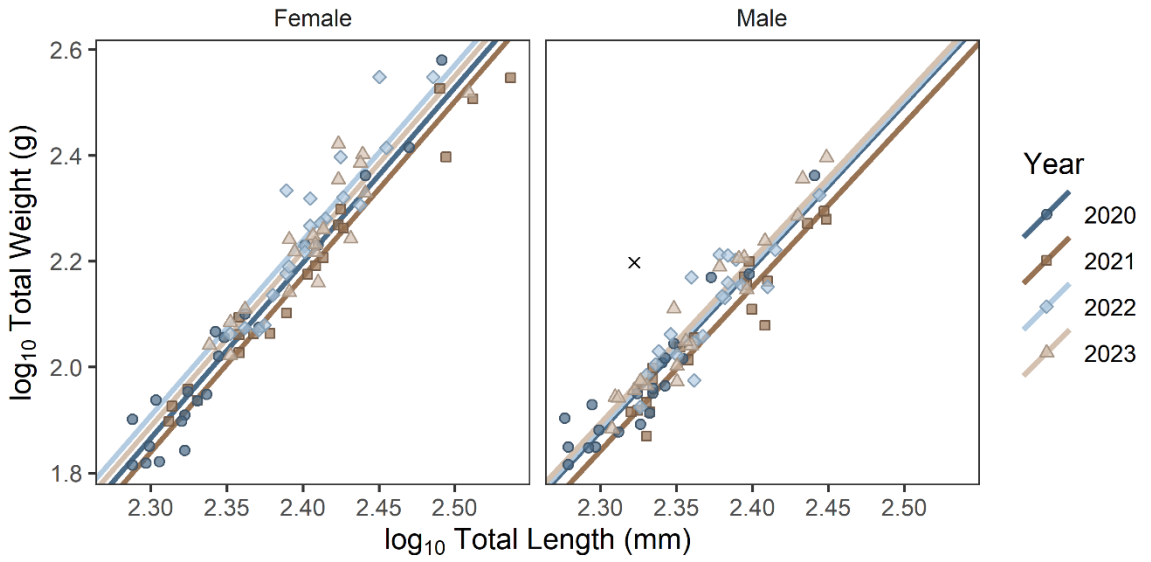


Figure 7-14: Size-at-Age Relationships for Female and Male Fourhorn Sculpin Sampled from the Milne Port Area, 2020 to 2023

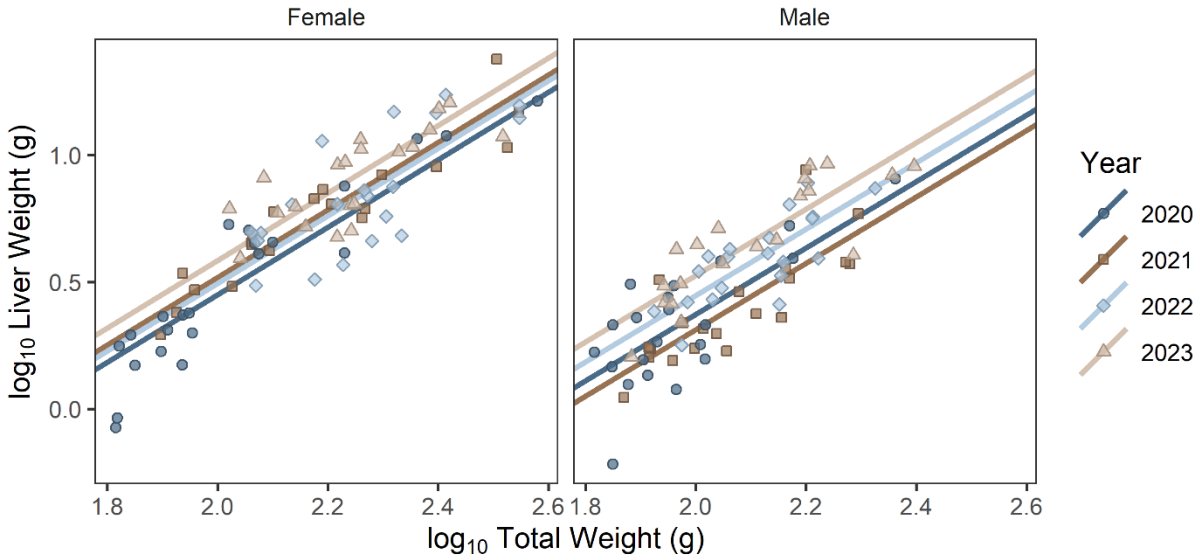
7.4.1.2.2.3 Condition – Relative Weight and Relative Liver Weight

Condition of Fourhorn Sculpin was compared between 2020, 2021, 2022, and 2023 using relative weight (as weight-at-length) and relative liver weight (as liver weight-at-total weight). Relative weight differed significantly among years for both sexes (Table 7-10; Figure 7-15). For female Fourhorn Sculpin, mean relative weight was similar between 2020 and 2021/2023, as wellas 2022 and 2023, but increased between 2020 and 2023 by approximately 10-16% (Table 7-10). For male Fourhorn Sculpin, relative weight varied among sampling years: generally, mean relative weights were not significantly different between 2020, 2022, and 2023, with a statistically significant decrease in 2021 compared to the other sampling years by 8-12% (Table 7-10). For females, condition factor from 2020 to 2023 ranged from 0.75 to 1.57; for males, condition factor in 2020, 2022, and 2023 ranged from 0.74 to 1.23, while in 2021, condition factor ranged from 0.71 to 1.01 (Table 7-7).

Relative liver weight differed significantly between years for both female and male Fourhorn Sculpin (Table 7-10; Figure 7-16). For female Fourhorn Sculpin, mean relative liver weight generally increased between 2020 to 2023 (by 31%), but no significant differences were observed among other years (Table 7-10). Similarly, for male Fourhorn Sculpin, relative liver weight was consistent between 2020 and 2021/2022, but increased between 2021 and 2022/2023, and 2020 and 2023, with the greatest relative percent difference between 2021 and 2023 of 48% (Table 7-10).

x = outlier.

Figure 7-15: Weight-at-Length Relationships for Female and Male Fourhorn Sculpin Sampled from the Milne Port Area, 2020 to 2023



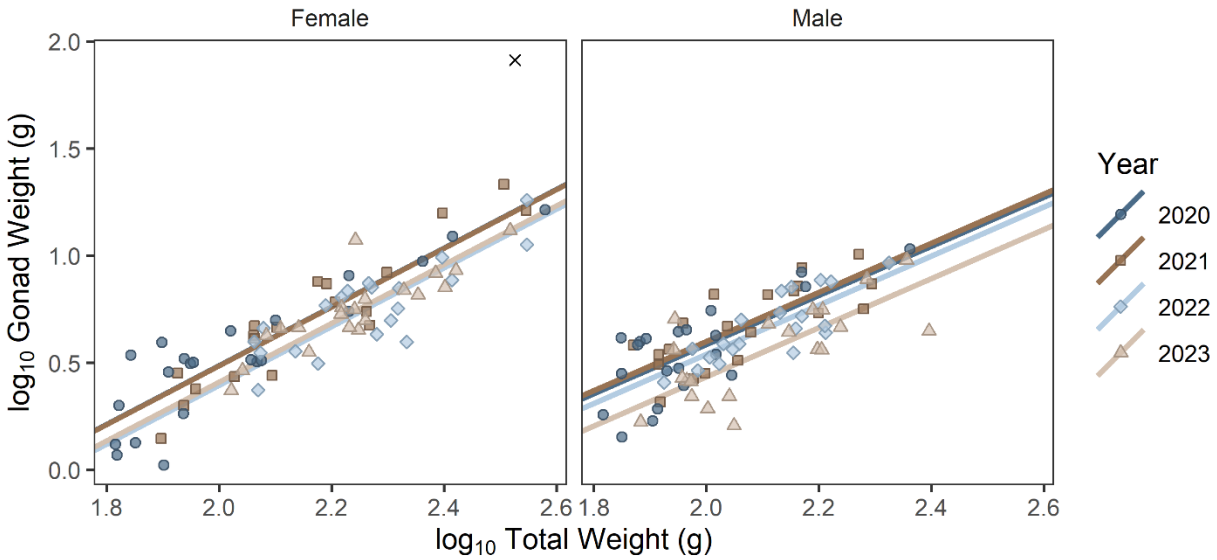


Figure 7-16: Relative Liver Weight for Female and Male Fourhorn Sculpin Sampled from the Milne Port Area, 2020 to 2023

7.4.1.2.2.4 Reproduction – Relative Gonad Weight

Relative gonad weights were compared between 2020, 2021, 2022, and 2023 using relationships between gonad weight and total weight in female and male Fourhorn Sculpin (Figure 7-17). Relative gonad weight differed significantly among sampling years for female Fourhorn Sculpin, but *post hoc* comparisons did not indicate significant pairwise differences[15] among years (Table 7-10). For male Fourhorn Sculpin, relative gonad weight was significantly lower in 2023 compared to previous sampling years (2020: 26%; 2021: 28%; 2022: 19%), which did not differ from each other (Table 7-10).

x = outlier.

Figure 7-17: Relative Gonad Weight for Female and Male Fourhorn Sculpin Sampled from the Milne Port Area, 2020 to 2023

[15] Statistical tests that compare multiple means, such as ANOVA and ANCOVA, test the null hypothesis that all group means (e.g., sampling year means) are equal to the overall mean using F-tests. A significant F-test result indicates that at least one group mean differs significantly from the overall mean, and this result is investigated using *post-hoc* pairwise comparisons that are adjusted for multiple comparisons. This adjustment is necessary to maintain the overall Type I error rate (i.e., $\alpha = 0.10$) when making multiple comparisons, but can result in no significant pairwise differences during *post-hoc* comparisons.

Table 7-10: Summary of Statistical Comparisons Between 2020, 2021, 2022, and 2023 for Fourhorn Sculpin, Milne Port Area

Effect Indicator	Endpoint[a]	Statistical Test	Sample Size				Least Squares Mean				Year *P*-value	*Post-hoc P*-value						Relative Percent Difference (%)						Power Analysis[b]

Notes: Statistically significant values are indicated in **bold**. Power analysis was completed assuming normality. Supporting information for statistical model results is provided in Appendix 7B, Table 7B-9. Statistical outliers are provided in Appendix 7B, Table 7B-10.

(a) For model components, please see Table 7-3.

(b) For log_{10}-transformed models, power analysis was completed for differences less than and greater than the mean. Minimum detectable difference and sensitivity were determined using back-transformed values and are presented as: differences lower than | greater than the mean.

(c) Minimum detectable difference expressed as difference from the overall mean.

(d) Sensitivity is the minimum detectable difference expressed as a percent change in the overall mean.

n = sample size; log_{10} = log_{10}-transformed data; rank = rank-transformed data; ANOVA = analysis of variance; ANCOVA = analysis of covariance; - = not calculated.

7.4.1.3 *Hiatella arctica*

In 2023, a total of 40 *H. arctica* collected from the Milne Port area were processed for fish health endpoints (Table 7-11). The processed individuals ranged in length from 24.3 mm to 37.8 mm, with a median length of 30.5 mm, and ranged in whole animal wet weight from 1.15 g to 7.07 g, with a median value of 3.91 g. Length data showed no skew or multimodality at Milne Port (Figure 7-18). Length exhibited a strong relationship with total weight ($P < 0.001$; $R^2 = 0.62$). Gonad weights ranged from 0.030 g to 0.346 g, with a median value of 0.098 g; mantle somatic index (MSI) ranged from 2.89 to 15.43 with a median value of 6.31. *Hiatella arctica* sampled from the Milne Port area ranged in age from 7 to 52 years, with a median age of 21. Median condition factor in 2023 was 1.79, ranging from 1.10 to 14.20.

Additional *H. arctica* were collected from the Tugaat River Estuary reference area in 2023, totalling 17 individuals. Collected *Hiatella* ranged in length from 19.0 to 39.0 mm, with a median length of 32.0 mm, and ranged in whole animal wet weight from 0.93 g to 10.5 g, with a median value of 4.10 g. Length data showed some multimodality, likely due in part to the smaller sample size (i.e., n = 17; Figure 7-18). Length exhibited a strong relationship with whole animal wet weight ($P < 0.001$; $R^2 = 0.87$). Gonad weights ranged from 0.037 g to 0.171 g, with a median value of 0.121 g; MSI ranged from 3.74 to 9.56, with a median value of 6.28. *Hiatella arctica* sampled from the Tugaat River Estuary reference area ranged in age from 5 to 76 years, with a median age of 14. Median condition factor in 2023 was 1.62, ranging from 1.18 to 2.29.

7.4.1.3.1 Spatial Comparisons

Hiatella arctica were collected from the Milne Port area and Tugaat River Estuary reference area in 2023. Fish health endpoints (Table 7-4) were compared among sampling areas. Biological data for *H. arctica* collected in 2023 are summarized in Table 7-11.

Table 7-11: Descriptive Statistics for Hiatella arctica Health Endpoints from the Milne Port Area and Tugaat River Estuary Reference Area, 2023

	Relative Shell Weight	Length	$ANCOVA_{log10}$	40	17	0.277	0.238	0.354	-	0.399 / 0.513	22% / 28%
Reproduction	Mantle Somatic Index	Soft Tissue Weight	$ANCOVA_{log10}$	40	17	-1.03	-1.01	0.783	-	0.001 / 0.001	21% / 27%

Notes: Statistically significant values are indicated in bold. Power analysis was completed assuming normality. Supporting information for statistical model results are provided in Appendix 7B, Table 7B-10.

(a) For model components, please see Table 7-4.

(b) The magnitude of effect is calculated as the difference in least squares mean values between Milne Port and Tugaat River Estuary: (Milne - Tugaat) / Tugaat × 100% (Environment Canada 2012).

(c) For log_{10}-transformed models, power analysis was completed for differences less than and greater than the mean. Minimum detectable difference and sensitivity were determined using back-transformed values and are presented as: differences lower than | greater than the mean.

(d) Minimum Detectable Difference expressed as difference from the overall mean.

(e) Sensitivity is the minimum detectable difference expressed as a percent change in the overall mean.

log_{10} = log_{10}-transformed data; K-S Test = Kolmogorov-Smirnov test; ANOVA = analysis of variance; ANCOVA = analysis of covariance; - = not applicable; nc = not calculated.

7.4.1.3.1.1 Survival – Length-Frequency Analysis

Length-frequency distributions of *H. arctica* were compared between Milne Port and Tugaat River Estuary (Figure 7-18). Results of the Kolmogorov-Smirnov tests indicate there was no significant difference in length-frequency distributions between areas for *H. arctica* (Table 7-12).

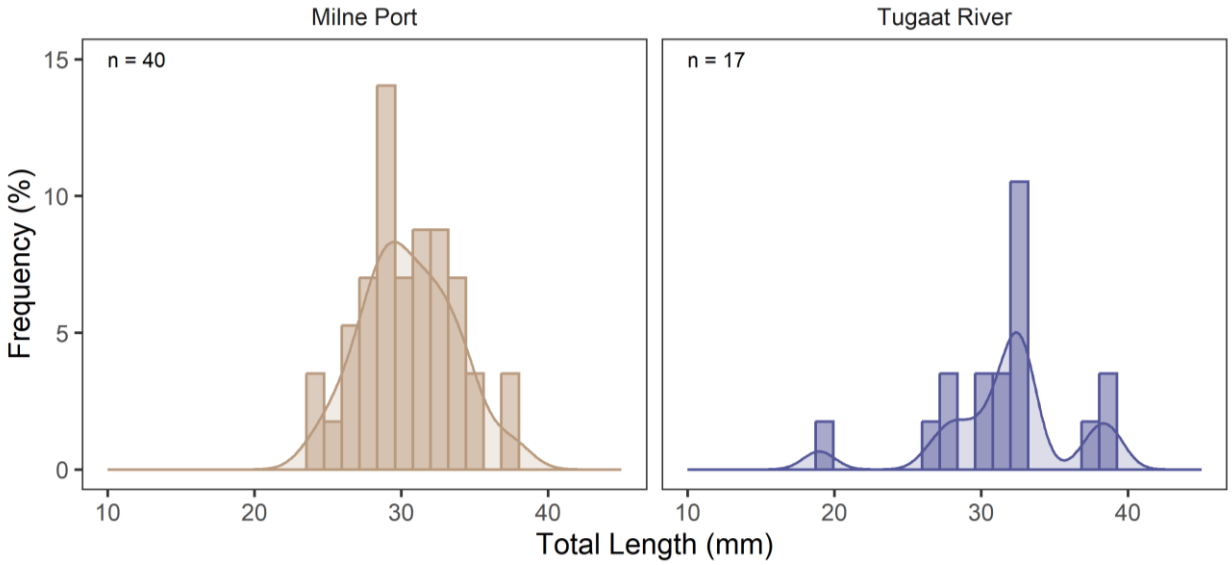

Figure 7-18: Length-Frequency Distribution for *Hiatella arctica* captured from the Milne Port Area and the Tugaat River Estuary Reference Area, 2023

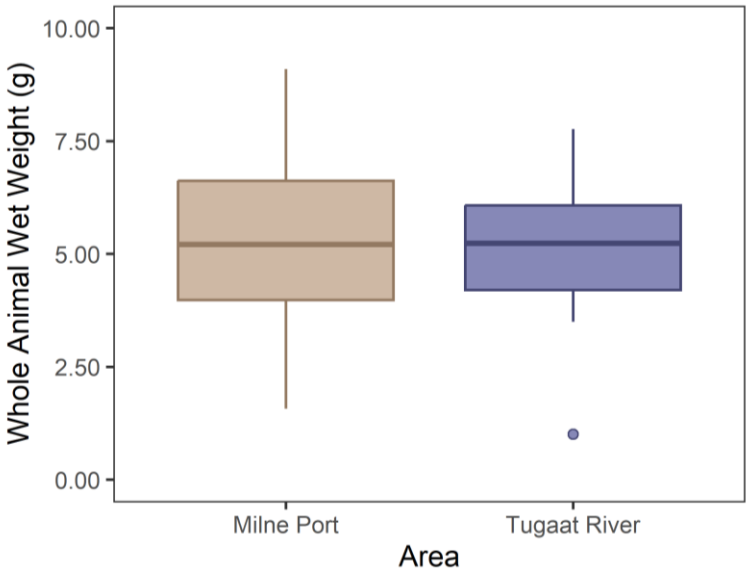
7.4.1.3.1.2 Growth – Whole Animal Wet Weight

Whole animal wet weight was compared between Milne Port and Tugaat River Estuary for *H. arctica* (Figure 7-19). The range of weights were similar among sampling years (Table 7-11), and there were no significant differences between sampling areas (Table 7-12).



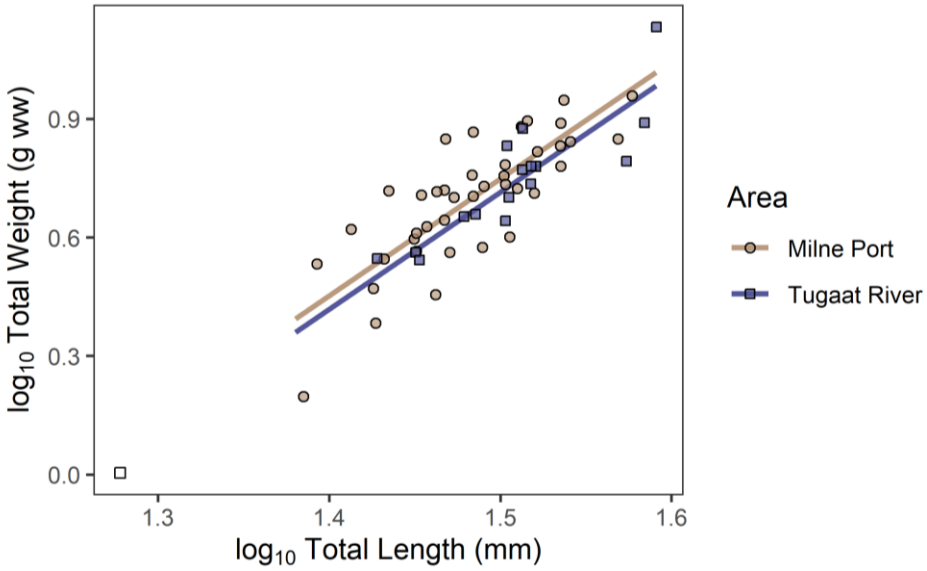


Figure 7-19: Boxplot of Whole Animal Wet Weight of *Hiatella arctica* captured from the Milne Port Area and the Tugaat River Estuary Reference Area, 2023

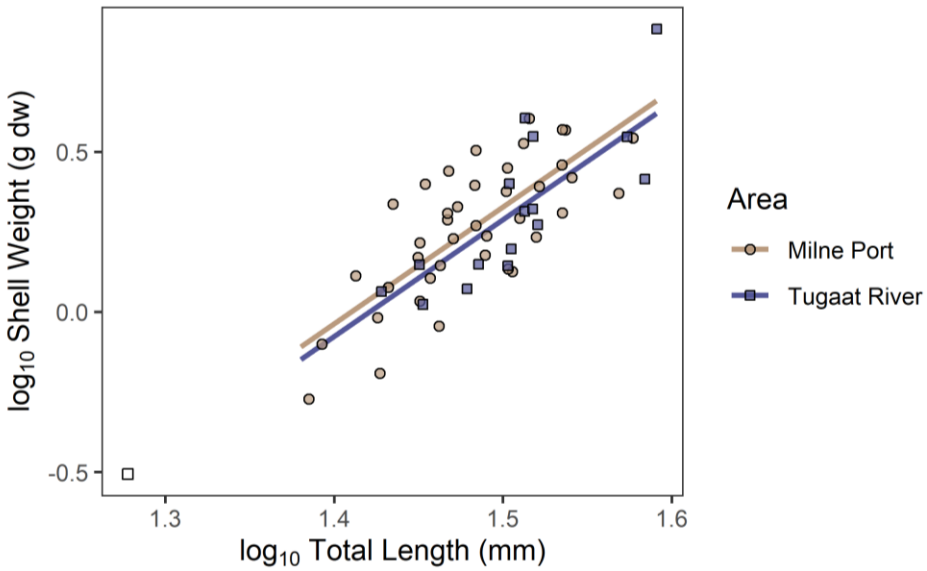

7.4.1.3.1.3 Condition – Relative Weight

Condition of *H. arctica* was compared between Milne Port and Tugaat River Estuary using relative weight (total weight-at-length) and relative shell weight (shell dry weight-at-length). Differences in relative weight and relative shell weight were evaluated over the shared range of lengths between sampling areas (i.e., 24 to 39 mm; Environment Canada 2012; Figure 7-20, Figure 7-21). Both relative weight and relative shell weight did not differ significantly among sampling areas (Table 7-12).

□ = omitted from ANCOVA.

Figure 7-20: Relationship between Total Weight and Total Length of *Hiatella arctica* Captured from the Milne Port Area and the Tugaat River Estuary Reference Area, 2023

□ = value omitted from ANCOVA.

Figure 7-21: Relationship between Shell Weight and Total Length of *Hiatella arctica* Captured from the Milne Port Area and the Tugaat River Estuary Reference Area, 2023

7.4.1.3.1.4 Reproduction – Mantle Somatic Index

Mantle somatic index of *H. arctica* was compared between Milne Port and Tugaat River Estuary: MSI was evaluated as relative gonad weight (gonad weight-at-tissue weight; Figure 7-22). Relative gonad weight did not differ between sampling areas (Table 7-12).

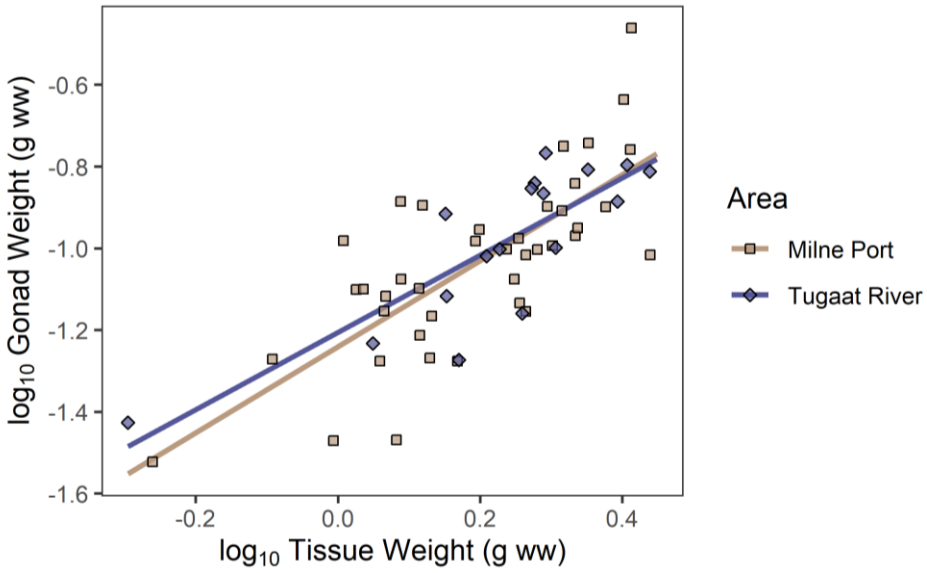

Figure 7-22: Relationship between Gonad Weight and Soft Tissue Weight of *Hiatella arctica* captured from the Milne Port Area and the Tugaat River Estuary Reference Area, 2023

Table 7-13: Summary of Statistical Comparisons for *Hiatella arctica* Health Endpoints at Milne Port between 2020, 2021, 2022, and 2023

Effect Indicator	Endpoint[a]	Covariate		Statistical Test	Sample Size				Least Squares Mean				Year *P*-value	Post-hoc *P*-value					Relative Percent Difference (%)						Power Analysis[b]	
					2020	2021	2022	2023	2020	2021	2022	2023		2020* 2021	2020* 2022	2020* 2023	2021* 2022	2021* 2023	2022* 2023	2020* 2021	2020* 2022	2020* 2023	2021* 2022	2021* 2023	2022* 2023	Minimum Detectable Difference[c]	Sensitivity[d]

Notes: Statistically significant values are indicated in bold. Power analysis was completed assuming normality. Supporting information for statistical model results are provided in Appendix 7B, Table 7B-11.

(a) For model components, please see Table 7-4.

(b) For log_{10}-transformed models, power analysis was completed for differences less than and greater than the mean. Minimum detectable difference and sensitivity were determined using back-transformed values and are presented as: differences lower than | greater than the mean.

(c) Minimum Detectable Difference expressed as difference from the overall mean.

(d) Sensitivity is the minimum detectable difference expressed as a percent change in the overall mean.

(e) *P*-values adjusted using Holm's correction for multiple comparisons (Holm 1979).

(f) ANCOVA completed only in range of overlapping total length between years (i.e., >25 mm) following Section A1.7 in Environment Canada (2012). See Figure 7-18 for *H. arctica* length-frequency distributions in 2020, 2021, 2022, and 2023.

(g) ANCOVA completed only in range of overlapping soft tissue weights between years (i.e., 0.61 to 2.87 g ww) following Section A1.7 in Environment Canada (2012).

(h) The R^2 value for the full model was less than the threshold (0.772 < 0.750) for assessing if slopes are practically parallel (Barrett et al., 2010); therefore, mantle somatic index was compared at the smallest and largest overlapping covariate values among study years, following Section A1.7 in Environment Canada (2012).

log_{10} = log_{10}-transformed data; K-S Test = Kolmogorov-Smirnov test; ANOVA = analysis of variance; ANCOVA = analysis of covariance; - = not applicable; nc = not calculated.

7.4.1.3.2 Temporal Comparisons

7.4.1.3.2.1 Survival – Length-Frequency

Length-frequency distributions of *H. arctica* were compared between years for 2020, 2021, 2022, and 2023 (Figure 7-23). Results of the Kolmogorov-Smirnov tests indicate there were no significant differences between years in length-frequency distributions for *H. arctica* (Table 7-13); however, the range of lengths was greater in 2021 than in 2020, 2022, or 2023 (Table 7-11), with more individuals less than 25 mm being collected.

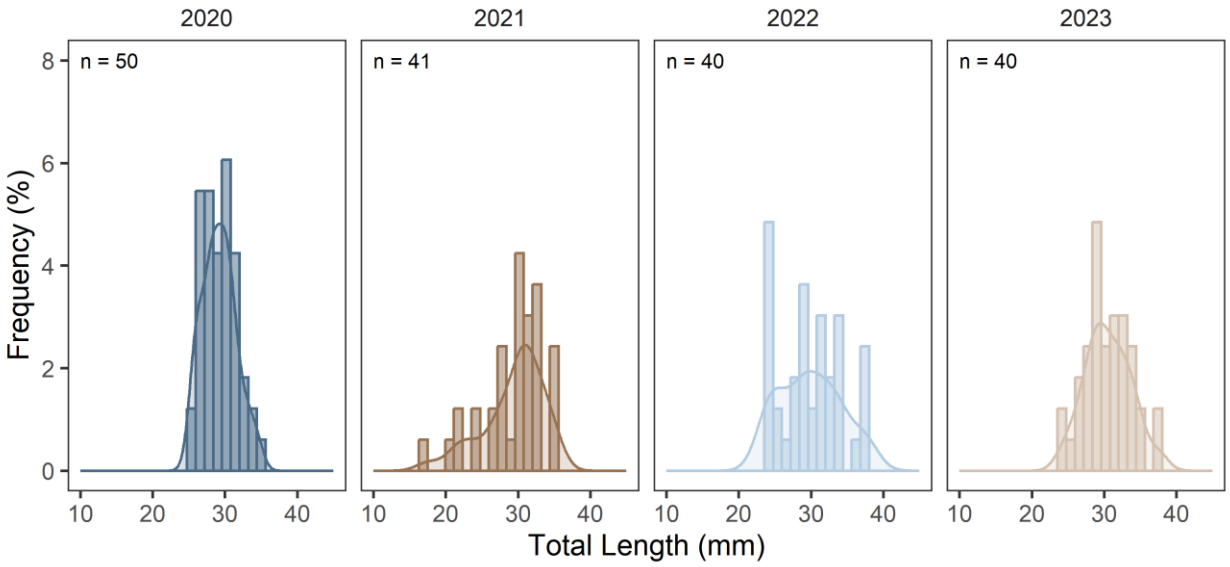

Figure 7-23: Length-Frequency Distribution for *Hiatella arctica* captured from the Milne Port Area, 2020 to 2023

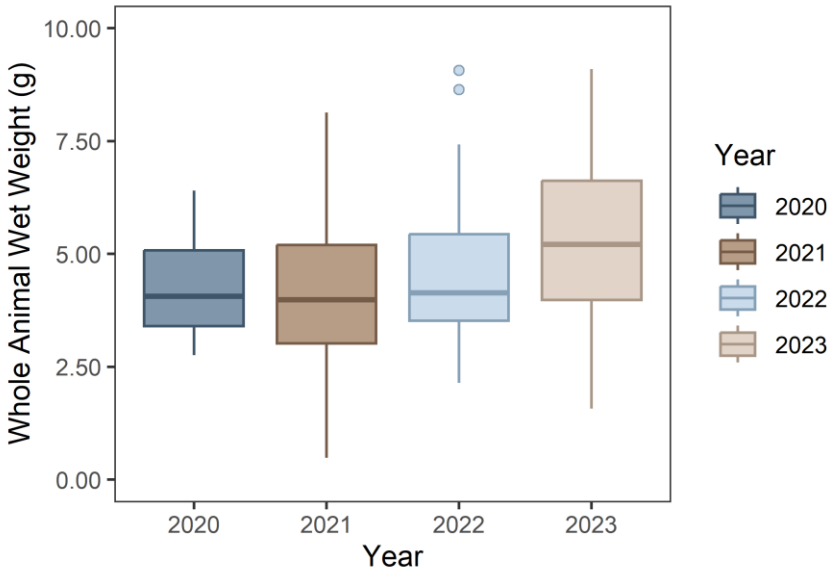
7.4.1.3.2.2 Growth – Whole Animal Wet Weight

Whole animal wet weight was compared among years for 2020, 2021, 2022, and 2023 for *H. arctica* (Figure 7-24). The range of weights were similar among sampling years; however, mean whole animal wet weight was significantly greater in 2023 compared to 2020 and 2021 (Table 7-11). No other significant differences between sampling years were observed.



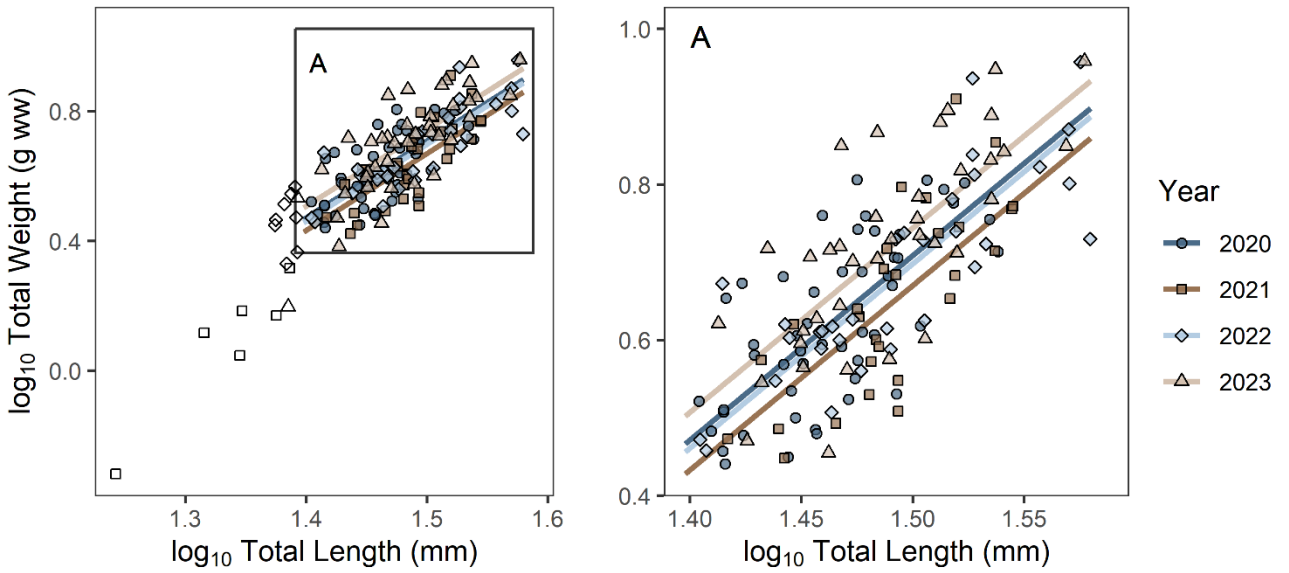


Figure 7-24: Boxplot of Whole Animal Wet Weight of *Hiatella arctica* captured from the Milne Port Area, 2020 to 2023

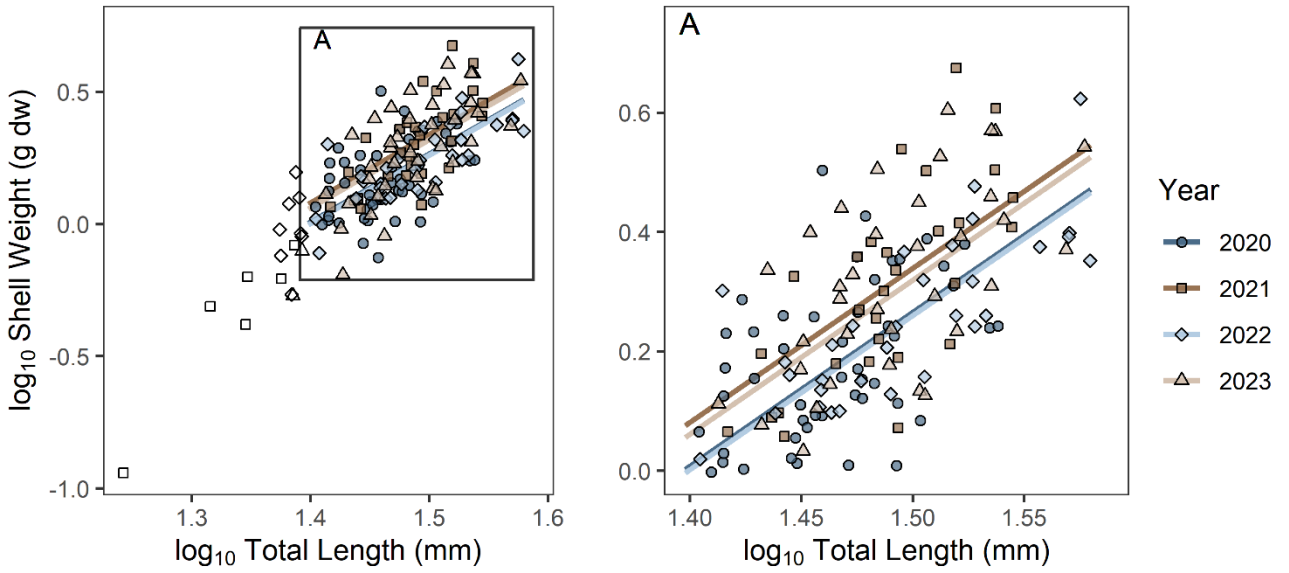
7.4.1.3.2.3 Condition – Relative Weight

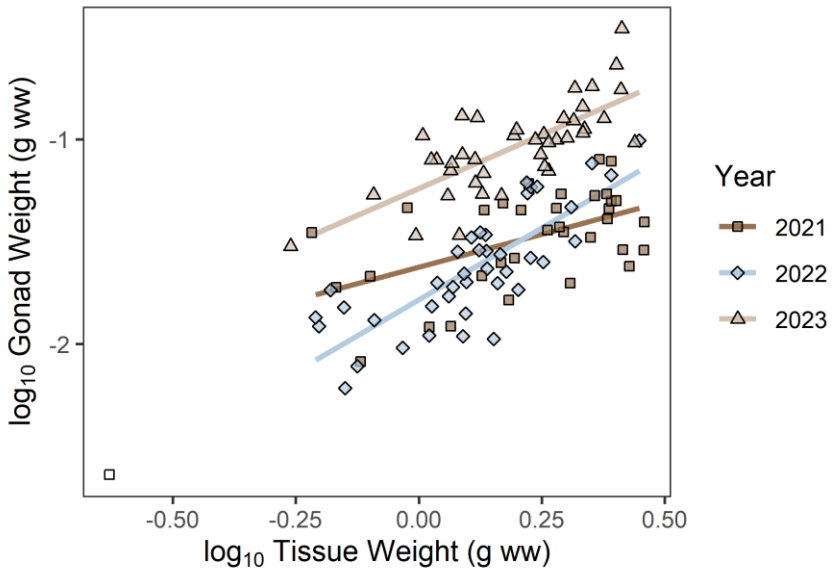


Condition of *H. arctica* was compared among years for 2020, 2021, 2022, and 2023 using relative weight (total weight-at-length) and relative shell weight (shell dry weight-at-length). Given the observed differences in the range of total length of *H. arctica* between years (Figure 7-23), differences in relative weight and relative shell weight were evaluated over the shared range of lengths (i.e., 25 to 38 mm; Figure 7-25), per Environment Canada (2012). Relative weight differed significantly among sampling years, with relative weight being greater in 2023 compared to 2021 and 2022 (Table 7-13). No other differences among sampling years were observed. Relative shell weight also differed significantly among sampling years (Figure 7-26): mean relative shell weight was greatest in 2020, declining from 2020 to 2022, then increasing marginally to 2023 (Table 7-13).

□, ◇, △ = values omitted from ANCOVA.

The portion of the data contained in inset 'A' is shown in more detail at right.

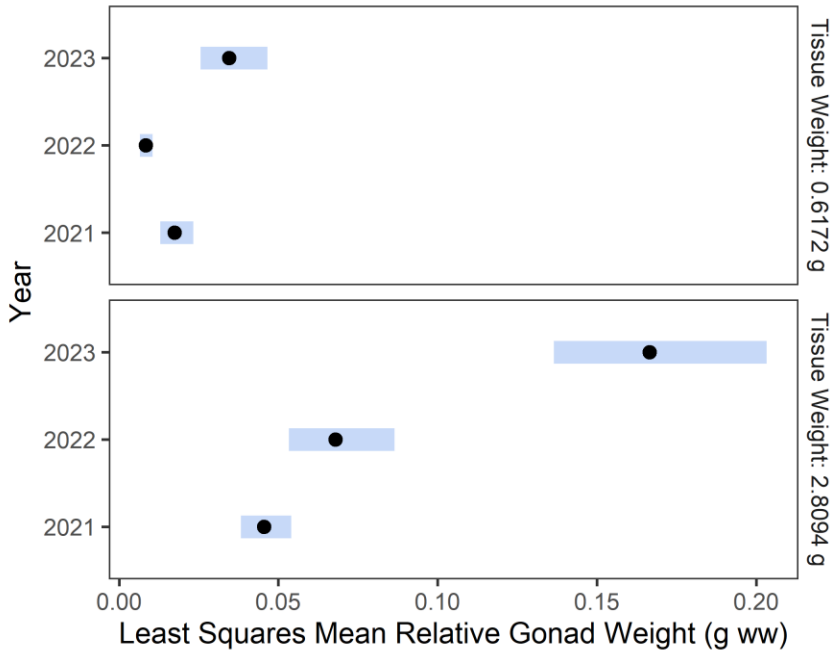
Figure 7-25: Relationship between Total Weight and Total Length of *Hiatella arctica* Captured from the Milne Port Area, 2020 to 2023



□, ◇, △ = omitted from ANCOVA.

The portion of the data contained in inset 'A' is shown in more detail at right.

Figure 7-26: Relationship between Shell Weight and Total Length of *Hiatella arctica* Captured from the Milne Port Area, 2020 to 2023



7.4.1.3.2.4 Reproduction – Mantle Somatic Index

Mantle somatic index (MSI) of *H. arctica* was compared between 2021, 2022, and 2023, as gonad tissues were not separated from other soft tissues in 2020. Mantle somatic index was evaluated as relative gonad weight (gonad weight-at-tissue weight; Figure 7-27). Relative gonad weight was evaluated at the least and greatest overlapping covariate values (i.e., tissue weights = 0.6172 g, 2.7505 g), due to a significant interaction term and relatively low R^2 values indicating slopes were not practically parallel (Table 7-13). At low tissue weight (-0.210 log units), relative gonad weight was greatest in 2023, followed by 2021, with the lowest relative gonad weight in 2022. At high tissue weight (0.439 log units), relative gonad weight was greatest in 2023, followed by 2020, with the lowest relative gonad weight in 2021.

□ = value omitted from ANCOVA.

Figure 7-27: Relationship between Gonad Weight and Soft Tissue Weight of *Hiatella arctica* captured from the Milne Port Area, 2021 to 2023

Values were back transformed from the log_{10} scale. Blue bars represent 90% confidence intervals. See Table 7-13 for statistical model information.

Figure 7-28: Least Squares Mean Relative Gonad Weights of *Hiatella arctica* Captured from the Milne Port Area, 2021 to 2023

Results of fish health analysis for Arctic Char, Fourhorn Sculpin, and *Hiatella arctica* were within FEIS predictions and FEIS addenda, which indicated the potential for low magnitude reductions in fish health and condition associated with release of site drainage. Results presented herein do not exceed predicted effects on fish health due to Project activities.

7.4.2 Fish Tissue Chemistry

A total of 389 fish tissue samples were submitted for metals analysis and 105 fish tissue samples were submitted for PAH analysis from the Milne Port area from 2010 to 2023. A summary of sample sizes by species and year are provided in Appendix 7C; Table 7C-1. The analyses presented herein focus on data collected since 2018. Summaries of tissue chemistry data collected in previous monitoring years are presented in Appendix 7C, Tables 7C-9 to 7C-11, and visual comparisons of the entire data series, including years prior to 2018, are shown as boxplots in Appendix 7D.

In 2023, a total of 24 samples from three species collected from the Milne Port area were submitted for metals analysis, supplementing data collected since 2018 to produce a dataset comprised of 333 samples for metals from the Milne Port area (i.e., Arctic Char [n = 105], Fourhorn Sculpin [n = 62], indeterminate sculpin [n = 30], and *H. arctica* [n = 136]). In addition, 12 samples from each of Fourhorn Sculpin and *H. arctica* collected from the reference areas were submitted for metals analysis in 2023. A total of 18 samples were analyzed for PAHs in 2023, supplementing data collected since 2020 to produce a dataset comprised of 104 samples for PAHs from the Milne Port area (i.e., Arctic Char [n = 50], Fourhorn Sculpin [n = 32], and *H. arctica* [n = 22]). In addition, a total of nine samples from Fourhorn Sculpin and *H. arctica* collected from the reference areas were submitted for PAH analysis in 2023. Results for individual species are described in the following sections.

7.4.2.1 Spatial Comparisons

7.4.2.1.1 Fourhorn Sculpin

Tissue Metals

In 2023, a total of 16 Fourhorn Sculpin tissue samples were analyzed for metals (i.e., eight samples from the Milne Port area and eight samples from the Koluktoo Bay reference area). Summary statistics for metals concentrations are provided in Table 7-14 and these results are presented as boxplots in Appendix 7D, Figures 7D-1 to 7D-31. Statistical comparisons for COPCs among sampling areas are provided in Table 7-15.

Concentrations of metals in Fourhorn Sculpin were generally similar between Milne Port and Koluktoo Bay (Appendix 7D, Figures 7D-1 to 7D-31), with a few exceptions. The range of measured concentrations of arsenic, lead, and manganese in samples from Koluktoo Bay appeared to be greater than the range of measured concentrations in Milne Port (Appendix 7D, Figures 7D-3, 7D-14, and 7D-16). These results are likely related to localized differences in water or sediment chemistry nearby the sampling area, and are considered to represent natural variability in the environment due to their association with the reference area. Concentrations of COPCs were generally not different between sampling areas, with the exception of selenium (Table 7-15). Mean selenium concentrations, adjusted for fish length, were significantly lower in Milne Port compared to Koluktoo Bay: the magnitude of effect was -12%. The direction of the observed difference does not support an effect attributable to Milne Port operations and was, therefore, not considered further.

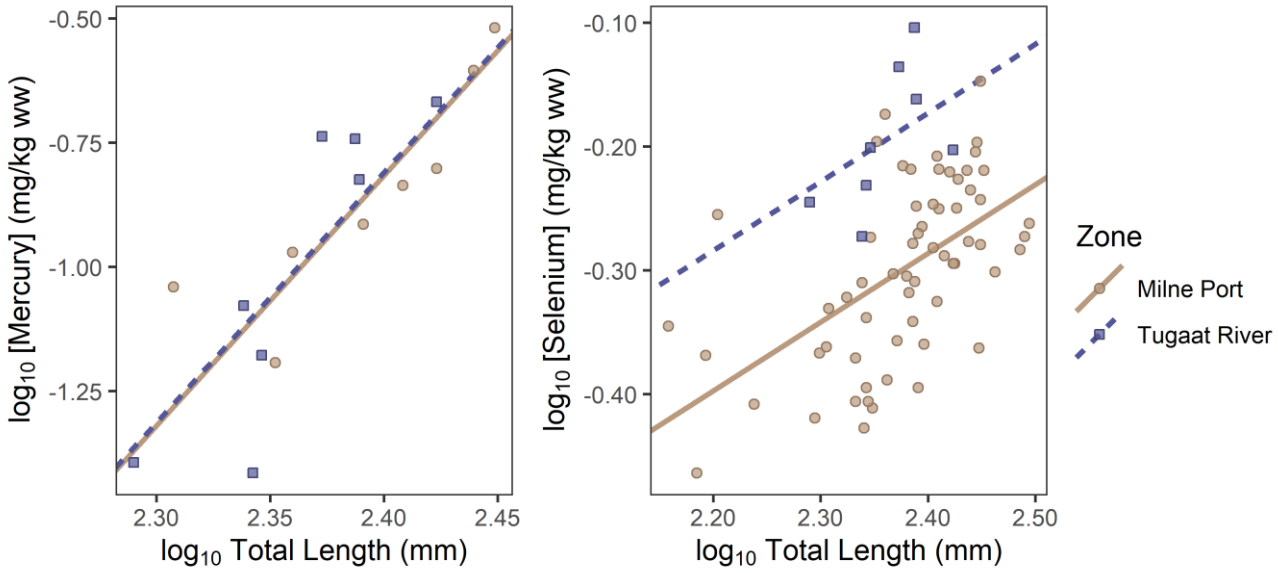


Figure 7-29: Concentrations of Mercury and Selenium in Relation to Total Length for Fourhorn Sculpin Sampled from the Milne Port Area and Koluktoo Bay Reference Area, 2023

Polycyclic Aromatic Hydrocarbons

In 2023, a total of 16 Fourhorn Sculpin tissue samples were analyzed for PAHs (i.e., eight samples collected from the Milne Port area and eight samples collected from the Koluktoo Bay reference area). The reported concentrations of PAHs were below DL for all parameters analyzed in Fourhorn Sculpin (Appendix 7C, Table 7C-7).

Results of chemical analyses of metals and PAHs in Fourhorn Sculpin tissues were within FEIS predictions and FEIS addenda, which indicated the potential for low magnitude increases in fish tissue concentrations of metals and/or PAHs associated with release of site drainage. Results presented herein do not exceed predicted effects on fish tissue chemistry due to Project activities.

Table 7-14: Descriptive Statistics for Fourhorn Sculpin Tissue Chemistry Data Analyzed from Milne Port Area and Koluktoo Bay Reference Area, 2023

Note: Significant differences indicated in **bold**. Supporting information for statistical model results are provided in Appendix 7C, Table 7C-12.

(a) Power Analysis values presented on measurement scale. Log_{10}-transformed models include values for differences below and above the grand mean.

(b) Minimum Detectable Difference expressed as difference from the overall mean.

(c) Sensitivity is the minimum detectable difference expressed as a percent change in the overall mean.

(d) Length was included as a covariate for ANCOVA and MLR.

ANOVA = analysis of variance; ANCOVA = analysis of covariance; log = log_{10}-transformed data; rank = rank-transformed data; - = not calculated, not applicable.

7.4.2.1.2 Hiatella arctica

Tissue Metals

In 2023, a total of 12 *H. arctica* samples were analyzed for metals (i.e., eight composite samples composed of shellfish collected from the Milne Port area, and four composite samples composed of shellfish collected from the Tugaat River Estuary reference area). Summary statistics for *H. arctica* metals concentrations are provided in Table 7-16 and are presented visually as boxplots in Appendix 7D, Figures 7D-1 to 7D-31. Statistical comparisons for COPCs among years are provided in Table 7-15.

Concentrations of metals in *Hiatella* were generally similar between Milne Port and Tugaat River Estuary, with a few exceptions. The range of measured concentrations of beryllium, lead, silver, and uranium in samples from the Tugaat River Estuary appeared to be greater than the range of measured concentrations in Milne Port (Appendix 7D, Figures 7D-5, 7D-14, 7D-23, and 7D-29). These results are likely related to localized differences in water or sediment chemistry nearby or upstream of the estuary, and are considered to represent natural variability in the environment due to their association with the reference area. Concentrations of COPCs were generally not significantly different between sampling areas, with the exception of magnesium (Table 7-15). Mean magnesium concentrations were significantly greater in samples from Milne Port compared to Tugaat River Estuary: the magnitude of effect was 82%, which is below the CES.

Polycyclic Aromatic Hydrocarbons

In 2023, a total of three *H. arctica* tissue samples were analyzed for PAHs, comprising two composite samples of shellfish collected from the Milne Port area and one composite sample composed of shellfish collected from the Tugaat River Estuary reference area. Samples were composited (i.e., multiple individual *H. arctica* combined into one sample) in order to meet minimum mass requirements for laboratory analyses. Polycyclic aromatic hydrocarbons were below DL for all parameters analyzed in *H. arctica* (Appendix 7C, Table 7C-8).

Results of chemical analyses of metals and PAHs in *Hiatella arctica* tissues were within FEIS predictions and FEIS addenda, which indicated the potential for low magnitude increases in fish tissue concentrations of metals and/or PAHs associated with release of site drainage. Results presented herein do not exceed predicted effects on fish tissue chemistry due to Project activities.

Table 7-16: Descriptive Statistics for *Hiatella arctica* Tissue Chemistry Data Analyzed from Milne Port Area and Tugaat River Estuary Reference Area, 2023

Parameter	Milne Port							Tugaat River Estuary

Data for previous monitoring years presented in Appendix 7C, Table 7C-10.

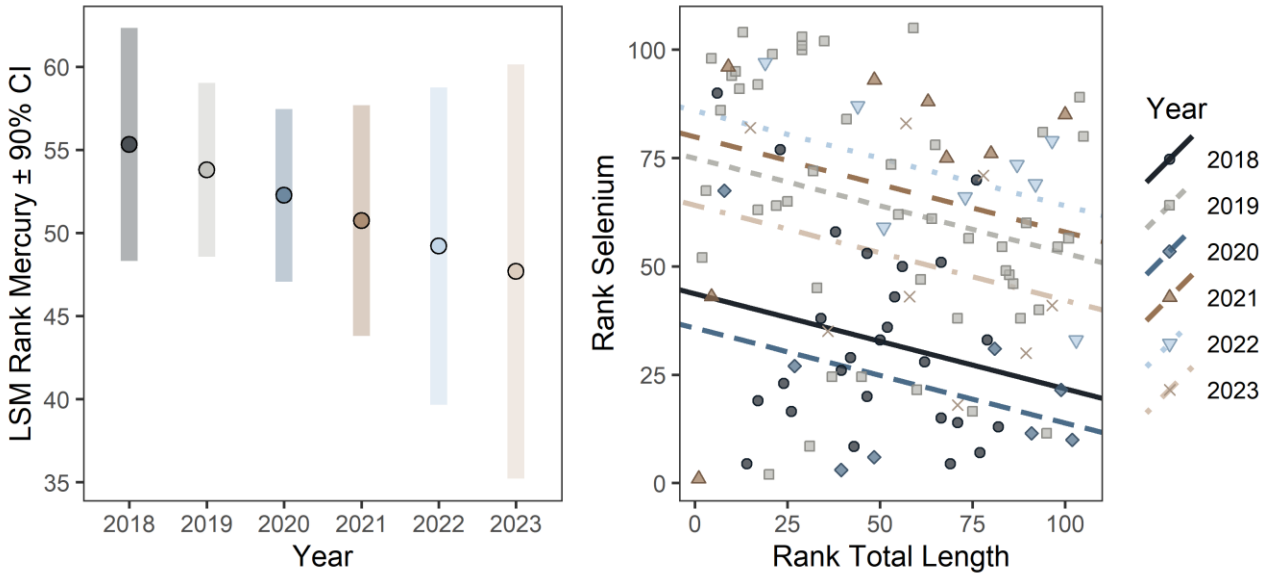
N > DL / N Total = number of samples above DL / sample size; mg/kg = milligram per kilogram wet weight; > = greater than; DL = detection limit; N = sample size; min = minimum; max = maximum; SD = standard deviation; SE = standard error.

7.4.2.2 Temporal Comparisons

7.4.2.2.1 Arctic Char

Tissue Metals

From 2018 to 2023, a total of 105 Arctic Char were analyzed for metals from the Milne Port area. Summary statistics for metals concentrations from Arctic Char collected in 2023 are provided in Table 7-17 (data from all years are presented as boxplots in Appendix 7D, Figures 7D-1 to 7D-31). Statistical evaluation of trends in COPCs (i.e., aluminum, iron, magnesium, mercury, and selenium) among years (i.e., 2018 to 2023) are provided Table 7-18 and Appendix 7C.



Concentrations of many metals were similar among years, however some demonstrated notable inter-annual variability (e.g., copper, iron, selenium, zinc; Appendix 7D, Figures 7D-1 to 7D-31). Among COPCs, no significant temporal trends were observed for aluminum, mercury, and selenium, while significant trends were observed among years for iron and magnesium (Table 7-18):

- Rank-transformed iron concentrations in Arctic Char demonstrated a significant increasing trend from 2018 to 2023. Median concentrations displayed interannual variability pre-2022, but increased between 2022 and 2023 (RPD: 44%) compared to previous years (Appendix 7D Figure 7D-13).
- Magnesium concentrations in Arctic Char demonstrated a significant increasing trend from 2018 to 2023. Median magnesium concentrations displayed interannual variability over the sampling period, increasing steadily from 2018 to 2022, with median concentration decreasing by approximately 6% in 2023 to levels comparable to those observed in 2019 and 2020 (Appendix 7D Figure 7D-15).

A power analysis for COPCs indicated that target sample sizes of eight Arctic Char of mixed sex per sampling area would be sufficient to detect differences in concentrations ranging from 9% for magnesium to 92% for aluminum (Table 7-18).

From 2018 to 2023, mercury concentrations showed no statistical relationship between fish length or weight in Arctic Char. Therefore, mercury concentrations in Arctic Char were evaluated for temporal trends without adjusting for a covariate (Figure 7-30): no significant temporal trends were observed (Table 7-18). In contrast, selenium concentrations were significantly, positively associated with fish length (Figure 7-30) and after adjusting for length, no significant temporal trends were observed (Table 7-18)

Mercury concentrations for all Arctic Char sampled from 2018 to 2023 were below Health Canada's Maximum Levels for Chemical Contaminants in Foods mercury consumption guideline of 0.5 mg/kg ww (Health Canada 2015), with tissue mercury concentrations ranging from 0.011 to 0.297 mg/kg ww. Selenium concentrations for Arctic Char were also below the BC MOE fish tissue guidelines of 4 mg/kg dw (BC MOE 2014), with tissue concentrations ranging from 0.912 to 3.19 mg/kg dw from 2018 to 2023.

LSM = least squares mean; CI = confidence interval.

Note: rank transformation results in unitless values.

Figure 7-30: Concentrations of Mercury and Selenium in Relation to Total Length for Arctic Char Sampled from the Milne Port Area, 2018 to 2023

Polycyclic Aromatic Hydrocarbons

From 2010 to 2022, a total of 56 Arctic Char were analyzed for polycyclic aromatic hydrocarbons (PAHs) from the Milne Port area. In 2023, a total of eight Arctic Char were analyzed for PAHs in muscle tissue. Concentrations of PAHs were below DLs for all parameters analyzed in Arctic Char (Appendix 7C, Table 7C-6).

Results of chemical analyses of metals and PAHs in Arctic Char tissues were within FEIS predictions and FEIS addenda, which are consistent with low magnitude increases in fish tissue concentrations of metals and/or PAHs associated with release of site drainage. These results do not exceed predicted effects on fish tissue chemistry due to Project activities.

Notes: Significant differences indicated in **bold**. Supporting information for statistical model results are provided in Appendix 7C, Table 7C-13.

(a) Slope directions are presented only for statistically significant trends.

(b) Least squares means were calculated using linear regression relationships for linear regression models for each sampling year. For rank-transformed models, rank least squares means are presented.

(c) For log_{10}-transformed models, power analysis was completed for differences less than and greater than the overall mean. Minimum detectable difference and sensitivity were determined using back-transformed values and are presented as: differences lower than / greater than the mean.

(d) Minimum Detectable Difference expressed as difference from the overall mean.

(e) Sensitivity is the minimum detectable difference expressed as a percent change in the overall mean.

(f) Length was included as a covariate for ANCOVA.

(g) Parameter concentrations were compared at 217 mm length due to narrow range of covariate overlap.

n = number; *P*-value = probability value; RPD = relative percent difference; LR = linear regression; ANOVA = analysis of variance; ANCOVA = analysis of covariance; log = log_{10}-transformed data; rank = rank-transformed data; - = not calculated.

7.4.2.2.2 Fourhorn Sculpin

Tissue Metals

A total of 62 Fourhorn Sculpin samples were analyzed for metals from the Milne Port area from 2019 to 2023, including 30 samples in 2019, eight in 2020, eight in 2021, eight in 2022, and eight in 2023. Summary statistics for metals concentrations in 2023 are provided in Table 7-14; results from all monitoring years are presented as boxplots in Appendix 7D, Figures 7D-1 to 7D-31 and as summary statistics in Appendix 7C, Tables 7C-9 to 7C-11. Statistical comparisons for COPCs among years are provided in Table 7-18.

Concentrations of metals in Fourhorn Sculpin were generally more variable than Arctic Char (Section 7.4.2.2.1). Significant trends in COPC concentrations were observed among years for aluminum and iron, but not for magnesium, mercury, or selenium (Table 7-18):

- Log-transformed aluminum concentrations in Fourhorn Sculpin demonstrated a significant decreasing trend from 2019 to 2023 (Table 7-18). Median concentrations were greatest in 2019, which declined and became more variable from 2020 to 2022, and declined again in 2023 (Appendix 7D, Figure 7D-1).
- Log-transformed iron concentrations in Fourhorn Sculpin demonstrated a significant decreasing trend from 2019 to 2023. Median concentrations were greatest in 2019, declined in 2020, and remained relatively stable until 2023 (Appendix 7D, Figure 7D-13).
- Mercury and selenium concentrations were significantly related to fish length (Figure 7-31Table 7-18). However, after adjusting for fish length, no significant trends in mean mercury or selenium concentrations were observed in Fourhorn Sculpin (Table 7-18).

A power analysis for COPCs indicated that target sample sizes of eight Fourhorn Sculpin per sampling area would be sufficient to detect differences in concentrations ranging from 13-15% for selenium to 65-186% for aluminum.

Mercury concentrations for all Fourhorn Sculpin sampled from 2019 to 2023 were below Health Canada's Maximum Levels for Chemical Contaminants in Foods mercury consumption guideline of 0.5 mg/kg ww (Health Canada 2015), ranging from 0.055 to 0.43 mg/kg ww. Selenium concentrations were also below BC MOE fish tissue guidelines of 4 mg/kg dw (BC MOE 2014), with tissue concentrations in Fourhorn Sculpin from the Milne Port area ranging from 1.72 to 3.57 mg/kg dw from 2019 to 2023.

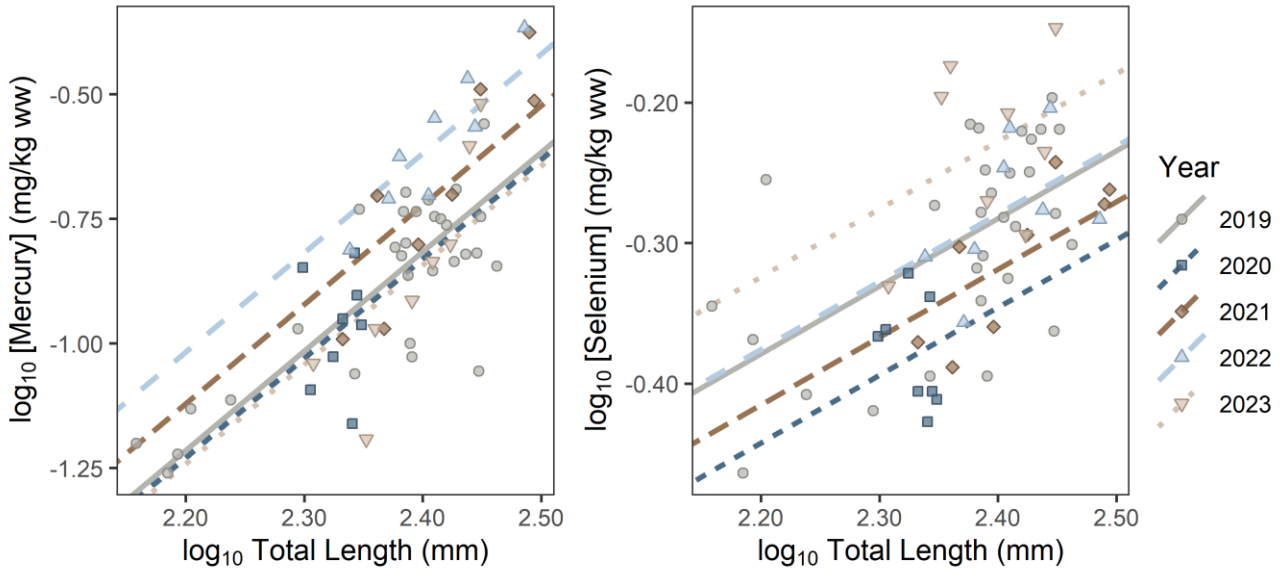

Figure 7-31: Concentrations of Mercury and Selenium in Relation to Total Length for Fourhorn Sculpin Sampled from the Milne Port Area, 2019 to 2023

Polycyclic Aromatic Hydrocarbons

From 2020 to 2023, a total of 32 Fourhorn Sculpin samples have been analyzed for PAHs, comprising eight samples per sampling year. In 2023, eight Fourhorn Sculpin were analyzed for PAHs in muscle tissue. Polycyclic aromatic hydrocarbons were below DL for all parameters analyzed in Fourhorn Sculpin (Appendix 7C, Table 7C-7).

Results of chemical analyses of metals and PAHs in Fourhorn Sculpin tissues were within FEIS predictions and FEIS addenda, which indicated the potential for low magnitude increases in fish tissue concentrations of metals and/or PAHs associated with release of site drainage. Results presented herein do not exceed predicted effects on fish tissue chemistry due to Project activities.

7.4.2.2.3 Hiatella arctica

Tissue Metals

A total of 136 *H. arctica* samples were analyzed for metals from the Milne Port area from 2018 to 2023, including 24 samples in 2018, 80 in 2019, eight in 2020, eight in 2021, eight in 2022, and eight in 2023. Summary statistics for *H. arctica* metals concentrations are provided in Table 7-16 and these results are presented as boxplots in Appendix 7D, Figures 7D-1 to 7D-31. Statistical comparisons for COPCs among years are provided in Table 7-18.

Concentrations of metals in *H. arctica* tissue were generally similar among years with a few exceptions. Chromium, nickel, and tin exhibited more variability and greater concentrations in 2020 relative to other years. Greater concentrations of most metals were observed for *H. arctica* when compared to Arctic Char and Fourhorn Sculpin (Appendix 7D, Figures 7D-1 to 7D-31). Differences in species-specific bioaccumulation processes (e.g., filter feeder versus non-filter feeder) and tissue type (i.e., whole body versus muscle) likely contributed to the

interspecies differences in tissue metal concentrations observed, with molluscs typically accumulating greater concentrations of some metals compared to fish (Bonsignore et al. 2018).

For COPCs, significant increasing trends in concentrations were observed for iron and selenium (Table 7-18). For iron, median concentrations increased from 2018 to 2019, after which they remained relative stable, showing only minor interannual variability (Appendix 7D, Figures 7D-13). The slope coefficient associated with the trend indicated iron concentrations have increased from 2018 to 2023. For selenium, median concentrations were relatively stable over time, showing minimal interannual variability (Appendix 7D, Figures 7D-22). However, the slope coefficient associated with the trend indicates selenium concentrations have increased from 2018 to 2023. The magnitude of observed trends are not considered ecologically relevant.

Concentrations of mercury and selenium in *H. arctica* were compared with fish tissue and invertebrate tissue guidelines, respectively. While the mercury guideline is not intended for bivalves, comparisons can provide consistent context for tissue chemistry results among the species monitored in the MEEMP. Mercury concentrations for all *H. arctica* sampled from 2018 to 2023 were below Health Canada's Maximum Levels for Chemical Contaminants in Foods mercury consumption guideline of 0.5 mg/kg ww (Health Canada 2015).

Polycyclic Aromatic Hydrocarbons

From 2020 to 2023, a total of 22 samples of *H. arctica* were analyzed for PAHs. In 2023, two samples of *H. arctica* were analyzed for PAHs in soft tissues in order to meet minimum mass requirements for laboratory analysis. Polycyclic aromatic hydrocarbons were below DLs for all parameters analyzed in *H. arctica* (Appendix 7C, Table 7C-8).

Results of chemical analyses of metals and PAHs in *Hiatella arctica* tissues were within FEIS predictions and FEIS addenda, which indicated the potential for low magnitude increases in fish tissue concentrations of metals and/or PAHs associated with release of site drainage. Results presented herein do not exceed predicted effects on fish tissue chemistry due to Project activities.

7.5 TARP Assessment

7.5.1 Fish Health

Results of fish health endpoint assessments were screened against the TARP criteria (Table 7-19). The 'Low Risk' threshold was exceeded for endpoints that were significantly different between Milne Port and the relevant reference area, with a magnitude of effect exceeding the CES. In addition, the direction of effect must be indicative of a potential impairment to fish health. In 2023, one fish health endpoint in Fourhorn Sculpin exceeded the 'Low Risk' threshold. Female Fourhorn Sculpin relative gonad weight was significantly different between Milne Port and Koluktoo Bay, and the associated effect size (-31%) exceeded the CES (±25%) in a direction indicative of an impairment to fish health. No additional endpoints for Fourhorn Sculpin and none of the fish health endpoints for *H. arctica* exceeded TARP thresholds.

Table 7-19: Comparison of Fish Health Endpoints for Fourhorn Sculpin and *Hiatella arctica* with TARP Thresholds, MEEMP 2023

TARP Performance Indicators	CES[(a)]	2023 MEEMP Results		Threshold Exceeded	
		Female	Male	Female	Male
Fourhorn Sculpin					
Age	±25%	=	Milne < Reference	None	None
Size-at-age (i.e., total weight at age)	±25%	**Milne > Reference**	**Milne > Reference**	None	None
Condition as relative weight (i.e., total weight at total length)	±10%	**Milne > Reference**	=	None	None
Relative liver weight (i.e., liver weight at total weight)	±25%	Milne < Reference	=	None	None
Relative gonad weight (i.e., gonad weight at total weight)	±25%	**Milne < Reference**	=	Low Risk	None
Hiatella arctica					
Length-frequency analysis	-	=		None	
Whole animal wet weight	-	=		None	
Condition as relative weight (i.e., whole animal wet weight at total length)	-	=		None	
Relative shell weight (i.e., dry shell weight at total length)	-	=		None	
Relative gonad weight (i.e., gonad weight at whole animal wet weight)	-	=		None	

Non-bolded values indicate a significant difference ($P < 0.10$) that does not exceed the CES. **Bold** values indicate a significant difference ($P < 0.10$) exceeding the CES. Underlined values indicate a magnitude of effect greater than the CES in a direction indicative of a potential impairment to fish health.

(a) There are no critical effect sizes associated with shellfish health endpoints (Environment Canada 2012).

TARP = Trigger Action Response Plan; '=' = no statistically significant difference ($P > 0.10$); '-' = not applicable.

7.5.2 Fish Tissue Chemistry

Results of fish tissue chemistry assessments were screened against the TARP criteria (Table 7-20). In 2023, concentrations of selenium in Fourhorn Sculpin and magnesium in *H. arctica* were significantly different between Milne Port and the relevant reference area (Koluktoo Bay and Tugaat River Estuary, respectively). However, the magnitudes of observed effects were below the CES (+100%) or in a direction not consistent with Project-related effects. Thus, no tissue chemistry endpoints exceeded TARP thresholds in 2023.

Table 7-20: Comparison of Fish Tissue Chemistry Endpoints for Fourhorn Sculpin and *Hiatella arctica* with TARP Thresholds, MEEMP 2023

TARP Performance Indicators	2023 MEEMP Results	Threshold Exceeded
Fourhorn Sculpin		
Aluminum	=	None
Iron	=	None
Magnesium	=	None
Mercury	=	None
Selenium	Milne < Reference	None
Hiatella arctica		
Aluminum	=	None
Iron	=	None
Magnesium	Milne > Reference	None
Mercury	=	None
Selenium	=	None

Unbolded values indicate a significant difference ($P < 0.10$) with a magnitude of effect below the CES. **Bold** values indicate a significant difference ($P < 0.10$) exceeding the CES.

TARP = Trigger Action Response Plan; '=' = no statistically significant difference ($P > 0.10$).

7.6 Discussion

7.6.1 Fish Health

Detailed fish health data were collected for Fourhorn Sculpin and *H. arctica* from Milne Port annually from 2020 to 2023 and from reference areas in 2023 (i.e., Koluktoo Bay [Fourhorn Sculpin] and Tugaat River Estuary [*H. arctica*]). In addition, biometric data for Arctic Char were collected from incidental mortalities from Milne Inlet in 2021, 2022, and 2023, to support the evaluation of Arctic Char health and condition. A summary of results of the fish health assessment for Fourhorn Sculpin and *H. arctica* is provided in Table 7-21 and Table 7-22, respectively.

Table 7-21: Summary of Results of Fish Health Assessment for Fourhorn Sculpin, MEEMP 2023

Fish Health Endpoint	CES	Fourhorn Sculpin	
		Female	Male
Spatial Comparisons			
Age	±25%	-	Milne < Reference (-20%)
Size-at-age (i.e., total weight at age)	±25%	Age 5: Milne > Reference (**37%**) Age 9: Milne > Reference (**84%**)	Milne > Reference (**50%**)
Condition as relative weight (i.e., total weight at total length)	±10%	Milne > Reference (**10%**)	-
Relative liver weight (i.e., liver weight at total weight)	±25%	Milne < Reference (-17%)	-
Relative gonad weight (i.e., gonad weight at total weight)	±25%	Milne < Reference (**-31%**)	-

Fish Health Endpoint	CES	Fourhorn Sculpin	
		Female	Male
Temporal Comparisons			
Age	n/a	Significant differences (15-33%) No trend	Significant differences (33%) 2022 > 2020
Size-at-age (i.e., total weight at age)	n/a	-	Significant differences (19-25%) 2023 > 2020, 2021
Condition as relative weight (i.e., total weight at total length)	n/a	Significant differences (10-16%) No trend	Significant differences (8-12%) No trend
Relative liver weight (i.e., liver weight at total weight)	n/a	Significant differences (31%) 2023 > 2020	Significant differences (35-48%) 2023 > 2020, 2021
Relative gonad weight (i.e., gonad weight at total weight)	n/a	-	Significant differences (24-38%) 2023 > 2020, 2021, 2022

The reference area for Fourhorn Sculpin is Koluktoo Bay. Magnitudes of effect (spatial comparisons) and relative percent differences (temporal comparisons) are presented in parentheses. **Bold** values indicate magnitudes of effect greater than the CES. Underlined values indicate magnitudes of effect exceeding the CES that are potentially indicative of an impairment to fish health.

CES = critical effect size; - = not significantly different; n/a = not applicable.

Table 7-22: Summary of Results of Fish Health Assessment for *Hiatella arctica*, MEEMP 2023

Fish Health Endpoint	CES[(a)]	Spatial Comparisons	Temporal Comparisons
Hiatella arctica			
Length-frequency analysis	n/a	-	-
Whole animal wet weight	n/a	-	Significant differences (20-27%) 2023 > 2020, 2021
Condition as relative weight (i.e., whole animal wet weight at total length)	n/a	-	Significant differences (11-17%) 2023 > 2021, 2022
Relative shell weight (i.e., dry shell weight at total length)	n/a	-	Significant differences (17-18%) 2021 > 2020, 2022
Relative gonad weight (i.e., gonad weight at whole animal wet weight)	n/a	-	Min Weight: Significant differences (66-122%) Max Weight: Significant differences (40-114%)

The reference area for *Hiatella arctica* is Tugaat River Estuary. Magnitudes of effect (spatial comparisons) and relative percent differences (temporal comparisons) are presented in parentheses.

(a) The CES is applied to spatial comparisons only.

CES = critical effect size; - = not significantly different; n/a = not applicable.

For Arctic Char, significant interannual differences were observed for condition factor. Mean condition factor was significantly lower in 2023 relative to 2022, but did not differ among other sampling years: the relative difference among years was approximately 12%. Observed variation in Arctic Char condition factor likely reflected natural variability attributable to seasonal and interannual differences in the Arctic Char population of Milne Inlet.

For Fourhorn Sculpin, several fish health endpoints differed between Milne Port and the Koluktoo Bay reference area (Table 7-21). In female Fourhorn Sculpin, relative gonad weight was significantly lower in Milne Port compared to Koluktoo Bay, and the magnitude of effect was greater than the CES: this resulted in a 'Low Risk' threshold exceedance. Similar results were not observed for male Fourhorn Sculpin. Temporal comparisons of female relative gonad weight indicated no differences among sampling years (i.e., 2018 to 2023). Mean gonadosomatic index (GSI), a metric for relative gonad weight, has varied by 2-39% (as RPD) among sampling years for female Fourhorn Sculpin from Milne Port. Field assessment of gonadal development indicates that sample timing is appropriate for assessing reproductive endpoints in Fourhorn Sculpin, as mature females have been captured during multiple MEEMP surveys. Given reference data for Fourhorn Sculpin were first collected in 2023, it is uncertain whether observed differences represent expected variability within the species or if differences are indicative of potential effects of localized stressors. Interannual variability in GSI has been observed in many marine and freshwater fish species (e.g., Albo-Puigserver et al. 2021, Dixon et al. 2020, Kjesbu et al. 1998, Melnikova and Kuzminova 2020, Mori et al. 2011) as populations respond to long-term environmental fluctuations: interannual variation in GSI exceeding 30% is not abnormal within a given population. The observed range of interannual variability and the absence of a consistent trend in relative gonad weight over time in Milne Port together suggest the observed difference in relative gonad weight for female Fourhorn Sculpin between Milne Port and Koluktoo Bay may be a result of interannual variability. Continued monitoring will provide additional insight into the variability of fish health endpoints for this fish species.

Hiatella arctica health endpoints did not differ between Milne Port and Tugaat River Estuary (Table 7-22), however, interannual differences in growth (whole animal wet weight), condition (relative weight and relative shell weight), and MSI all differed significantly among sampling years. Relative differences ranged from 11% for relative weight to 122% for mantle somatic index. Given the limited data currently available for *H. arctica* in Milne Inlet (i.e., three years) and for Tugaat River Estuary (i.e., two years), it is uncertain whether observed differences represent expected variability within the species or if differences are indicative of potential effects of localized stressors. Given the wide range of ages reported in the sampled population of *H. arctica* from both Milne Port and Tugaat River Estuary (i.e., 7 to 76 years), it is expected that growth and condition would vary within the species depending on stage of life. In the absence of significant differences in *H. arctica* health between Milne Port and Tugaat River Estuary in 2023, it is assumed that differences among sampling years represent natural variability within *H. arctica*.

Sample timing of *H. arctica* appears to be appropriate for assessing reproductive endpoints, as gonads were retrieved from collected samples in 2021, 2022, and 2023 from Milne Port, and in 2022 and 2023 from Tugaat River Estuary. Timing of spawning for *H. arctica* may be associated with phytoplankton biomass and varies with geographical location (Brandner et al. 2017). Gonadal development for this species may also be asynchronous, with multiple overlapping spawning events occurring throughout the year, potentially leading to a high degree of variability in gonad size regardless of sample timing. While MSI data from 2023 do not exhibit high variability, observed differences between 2021, 2022, and 2023 suggest interannual variability in gonadal development. Additional data collected in future years will improve understanding of the variability in gonadal development for *H. arctica*.

Results of the fish health analysis for Arctic Char, Fourhorn Sculpin, and *Hiatella arctica* were within FEIS predictions and FEIS addenda, which indicated the potential for low magnitude reductions in fish health and condition associated with release of site drainage. Results presented herein do not exceed predicted effects on fish health due to Project activities.

7.6.2 Tissue Chemistry

A total of 36 metals and 27 PAH samples were submitted for tissue chemistry analysis in 2023, including 24 metals and 18 PAH samples from Milne Port and 12 metals and nine PAH samples from the reference areas. Metal concentrations were generally above DLs and variable among species and years. In 2023, concentrations of most COPCs did not differ significantly between Milne Port and the reference areas for Fourhorn Sculpin and *H. arctica*. There were statistically significant differences among years in most COPCs, but the magnitudes of differences were relatively small, and the measured concentrations of COPCs in 2023 remained within the range of historical variability for all species. Temporal trends in COPCs were rarely observed, indicating identified differences were likely a result of interannual variability, and the magnitude of trends were considered not ecologically relevant.

All tissue samples for Arctic Char, Fourhorn Sculpin and *H. arctica* collected from 2018 to 2023 were below Health Canada's Maximum Levels for Chemical Contaminants in Foods mercury consumption guideline of 0.5 mg/kg ww (Health Canada 2015). All tissue samples for Arctic Char and Fourhorn Sculpin were also below BC MOE fish tissue guidelines of 4 mg/kg dw for selenium (BC MOE 2014).

A summary of results of the fish tissue chemistry assessment for Arctic Char, Fourhorn Sculpin, and *H. arctica* is provided in Table 7-23.

Table 7-23: Summary of Results of Fish Tissue Chemistry Assessment for Arctic Char, Fourhorn Sculpin, and *Hiatella arctica*, MEEMP 2023

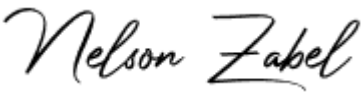
Tissue Chemistry Endpoint	CES[(a)]	Spatial Comparisons	Temporal Comparisons
Arctic Char			
Aluminum	100%	n/a	-
Iron	100%	n/a	Increasing trend
Magnesium	100%	n/a	Increasing trend
Mercury	100%	n/a	-
Selenium	100%	n/a	-
Fourhorn Sculpin			
Aluminum	100%	-	Decreasing trend
Iron	100%	-	Decreasing trend
Magnesium	100%	-	-
Mercury	100%	-	-
Selenium	100%	Milne < Reference (-12%)	-
Hiatella arctica			
Aluminum	100%	-	-
Iron	100%	-	Increasing trend
Magnesium	100%	Milne > Reference (82%)	-
Mercury	100%	-	-
Selenium	100%	-	-

As Arctic Char are highly mobile pelagic fish, there is no reference area for Arctic Char. The reference area for Fourhorn Sculpin is Koluktoo Bay, and the reference area for *Hiatella arctica* is the Tugaat River Estuary. Magnitudes of effect (spatial comparisons) and relative percent differences (temporal comparisons) are presented in parentheses.
(a) The CES is applied to spatial comparisons only.
CES = critical effect size; - = not significantly different; n/a = not applicable.

Concentrations of metals in sedentary, filter-feeding organisms like *H. arctica* tend to reflect the environment in which they live (Bonsignore et al. 2018; Checa et al. 2007; Shumway 1977). Concentrations of magnesium in *H. arctica* from Milne Port were significantly greater than concentrations at Tugaat River Estuary. Magnesium is an essential element for life, functioning as a key metal involved with cellular function, metabolism, energy storage and transfer, and enzyme function (Gaál et al. 2004; Rubin 1975; Wolf and Cittadini 1999). In bivalves, magnesium is also used for shell development, incorporated as the calcareous mineral aragonite (Dodd 1967; Checa et al. 2007). Given the vital role magnesium plays in living tissues, organisms are capable of bioregulating magnesium concentrations in their tissues. Differences in water chemistry between Tugaat River Estuary and Milne Port are likely contributing to observed differences in tissue chemistry.

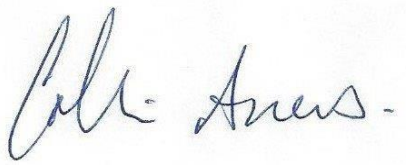
Consistent with previous years, concentrations of most metals were greater in *H. arctica* compared to Arctic Char and Fourhorn Sculpin. Molluscs tend to accumulate metals (from both natural and anthropogenic sources) to a greater degree compared to fish (Bonsignore et al. 2018), and this phenomenon is reflected in the *H. arctica* tissue chemistry results. Metals concentrations in *H. arctica* were consistently greater than those measured in Arctic Char and Fourhorn Sculpin, occasionally by orders of magnitude. Species-specific differences in bioaccumulation processes and the tissue types analyzed (i.e., whole body versus muscle) contribute to the differences observed in tissue metals concentrations among the monitored species. *Hiatella arctica* is a long-lived, sedentary, filter feeding mollusc closely associated with the sediment; these life-history characteristics increase the potential of *H. arctica* exposure to, and subsequent accumulation of, metals. The concentrations of metals and the observed trends reported herein in *H. arctica* are not considered to reflect ecologically relevant changes.

Tissue concentrations of PAHs were below DL for all Arctic Char, Fourhorn Sculpin, and *H. arctica* analyzed in 2023, consistent with previous monitoring programs. These results are consistent with water and sediment quality monitoring results, for which concentrations of PAHs were consistently below DL (Chapters 2.0, 3.0).



In summary, each sentinel fish species provides valuable information for the MEEMP. Arctic Char, a highly mobile and valued subsistence and commercial food fish species, provides ecologically relevant information regarding potential risk to human consumers, as well as large mammals. Fourhorn Sculpin, a benthic-dwelling species with a relatively small range, is an abundant fish species in the Project area, providing information on potential localized effects due to Project activities. Lastly, *H. arctica* have different feeding and life history strategies and, therefore, exposure potential compared to the finfish species. *Hiatella arctica* represent sedentary organisms, spending nearly their entire lives in one place. Their filter-feeding strategy results in continuous exposure to potential Project-related impacts on water quality, providing valuable information concerning potential risk to the benthic invertebrate and shellfish communities.

Results of chemical analyses of metals and PAHs in tissues from all species (Arctic Char, Fourhorn Sculpin, *Hiatella arctica*) were within FEIS predictions and FEIS addenda, which indicated the potential for low magnitude increases in fish tissue concentrations of metals and/or PAHs associated with release of site drainage. Results presented herein do not exceed predicted effects on fish tissue chemistry due to Project activities.



7.7 Conclusions and Recommendations

The MEEMP has been designed to meet the objectives of the various conditions associated with PC No. 005 (Chapter 1.0, Table 1-2), and to provide data and results to evaluate whether the marine environment is changing over time as a result of the Project. Original FEIS predictions, and FEIS addenda, indicated the potential for low magnitude changes in some ecological parameters, such as water quality and Arctic Char tissue chemistry, but characterised these changes as not ecologically significant. Monitoring data align with these predictions overall, as observed changes have been small and are consistent with baseline data or established guidelines. Monitoring to date suggests that Project mitigation is functioning as intended and that Project activities are being managed in a way that has not adversely affected marine fish health beyond the scope of the FEIS predictions, including addenda. Moving forward, continued monitoring of proposed MEEMP components is recommended to maintain continuity in established time series data for Arctic Char, and the ongoing collection of fish health and tissue chemistry data for Fourhorn Sculpin and *H. arctica* from Milne Port and relevant reference areas. These efforts will provide an ongoing dataset for use in monitoring effects of the Project to the marine environment into the future.

FISH HEALTH PROGRAM – 2023 KOLUKTOO BAY REFERENCE AREA RECONNAISSANCE

1.0 INTRODUCTION

One of the monitoring objectives for the 2023 MEEMP included a reference area reconnaissance survey. The selection of an appropriate reference area for the fish health and tissue chemistry program is necessary to support the MEEMP in future years and the incorporation of the Trigger Action Response Plan (TARP) as an adaptive management tool for the MEEMP program. To meet this objective, fish sampling was conducted in Koluktoo Bay (17W 509027m E 7997614m N; Figure 7A-1) in 2023 to evaluate whether the area was suitable for use as reference areas for Milne Port. *Hiatella arctica* sampling was conducted south of the Tugaat River (17X 0522444m E 7996648m N) as part of MEEMP study design.

The Tugaat River estuary was sampled for fish and *H. arctica* in 2021 and 2022 with Tugaat River fish sampling also conducted in 2022; reference area reconnaissance memos were included as Appendix 7A to the 2021 and 2022 MEEMP reports (Golder 2022; WSP Canada Inc. 2023). Given previous success at the Tugaat River estuary in collecting *H. arctica* but the limited success of targeted fish captures (Golder 2022; WSP Canada Inc. 2023), Tugaat River was deemed an appropriate reference area for *H. arctica* for the 2023 open-water season and was incorporated into the MEEMP Report Chapter 7.0 for the first time in 2023 (Sections 7.4 and 7.5). Supporting water and sediment quality sampling that occurred during sampling efforts in 2021 and 2023 was also incorporated into the report.

The 2023 reference area reconnaissance sampling program was completed concurrently with the 2023 MEEMP field program. The north shore of Koluktoo Bay was chosen for further reconnaissance given limited fishing success there during the 2022 reference area reconnaissance (WSP Canada Inc. 2023). Water quality, sediment quality, and fish community sampling was undertaken as part of the reconnaissance survey. Additionally, in an attempt to consolidate the reference areas, *H. arctica* sampling was attempted in Koluktoo Bay but no specimens were collected; therefore, the *H. arctica* reference area remained at the Tugaat River estuary. Koluktoo Bay does not represent a permanent addition to the MEEMP study design at this time, pending confirmation of the value of the Bay as a fish reference area.

2.0 WATER QUALITY

Exploratory water quality sampling was completed on 8 August 2023 alongside the 2023 MEEMP field program. Field water quality measurements and water samples were collected at one station, KLK-23, on the north shore of Koluktoo Bay (Figure 7A-1).

2.1 Sampling Methods

A depth sounder was used to measure depth at the reference location prior to sampling. Field water quality measurements (i.e., pH, dissolved oxygen, salinity, conductivity, temperature, and turbidity) were taken just above the sediment surface at a depth of 1 m due to the shallow depth in the area (-1.1 m Chart Datum), using a calibrated water quality meter. Water samples were collected just below the surface from the Baffinland research vessel using a 2.0 L vertically oriented Kemmerer bottle sampler. The sampler was washed with laboratory-grade detergent and then rinsed with site-water prior to sample collection at the station. Samples were preserved in the field according to laboratory instructions. Samples for dissolved analyses were filtered in the field using 0.45 µm filters. Samples were kept refrigerated until they were shipped on ice in coolers within 48 hours to ALS Canada Ltd. (ALS), a Canadian Association for Laboratory Accreditation Inc. (CALA) accredited analytical laboratory. Water samples were submitted for analysis of the parameters measured at Milne Port in 2023 (Section 2.2.1) including major ions, nutrients, total and dissolved organic carbon, and total and dissolved metals.

2.2 Data Analysis

Water quality data collected at KLK-23 were screened against the applicable Canadian Council of Ministers of the Environment (CCME) water quality guidelines for the protection of marine aquatic life (CCME 1999, CCME 2002). A comparison was also made to water quality data collected at Milne Port in 2023 (Section 2.3.2).

2.3 Quality Assurance/Quality Control

A field duplicate sample was collected at KLK-23 on 08 August 2023. Laboratory quality assurance/quality control (QA/QC) reports were reviewed upon receipt to confirm adherence to sample hold times and laboratory data quality objectives (DQOs), and that the appropriate QA/QC information had been reported. Laboratory QA/QC included verification of recommended sample holding times and the analysis of laboratory control samples, laboratory duplicates, and spiked samples to assess precision and accuracy of analytical methods. In addition, QA/QC assessments are included in Chapter 2 Marine Water Quality and Appendix 2D, which are applicable to the reference area reconnaissance sampling described herein.

2.3.1 QA/QC Results

The 2023 water quality data for the reference area reconnaissance at Koluktoo Bay were considered valid and of acceptable quality to address the reconnaissance study objective, according to the following rationale:

- Analysis of water quality samples was completed within sample hold time requirements. The only exceptions were nitrate, nitrite, pH, and turbidity. Exceedances of holding times are common for these parameters when shipping samples from remote sampling locations.
- Data reported by the laboratory were considered reliable according to the accredited laboratory QA/QC assessment.
- Results of duplicate comparisons using RPD indicated results were within data quality objectives (<20% RPD), with one exception: the RPD for turbidity between the parent sample and the duplicate (41%) exceeded the data quality objective.

The QA/QC results indicate that the water chemistry data collected during the reconnaissance area sampling were of acceptable quality. See Chapter 2.0 Marine Water Quality and Appendix 2D for further information regarding QA/QC assessment results.

2.4 Results and Discussion

Parameter concentrations measured in water quality samples collected in the Koluktoo Bay at KLK-23 were below CCME Aquatic Life Freshwater (AW-F) guidelines and within the concentration ranges documented for Milne Port in 2023 (see Table 7A-1). Similarly, dissolved oxygen, salinity, and temperature measurements at 1 m depth (i.e., just above the sediment surface) were within ranges measured at MP05 and MP06 in Milne Port in 2023 (see Table 2-1 in Section 2.2.1). Water quality in Koluktoo Bay was considered comparable to Milne Port water quality based on this evaluation of water quality data collected during the 2023 open-water season.

Table 7A-1 Water Quality Laboratory Results in Koluktoo Bay, 2023

CCME = Canadian Council of Ministers for the Environment; mg/L = milligrams per litre; < = below detection limit; - = no data; * = short-term exposure guideline for silver; NA = not applicable; NC = not calculated.

Bold, outline and blue shaded Exceeds CCME AW-F guidelines for protection of marine aquatic life

1. Canadian Council of Ministers of the Environment (CCME 1999, updated to 2019) water quality guidelines for the protection of marine aquatic life.

3.0 SEDIMENT QUALITY

Exploratory sediment quality sampling was completed on 8 August 2023 alongside the 2022 MEEMP field program. Sediment samples were collected at one station, KLK-23, on the north shore of Koluktoo Bay (Figure 7A-1).

3.1 Sampling Methods

Sediment samples were collected using a Van Veen (0.1 m^2) grab sampler. At the sampling location, a grab sample and a duplicate were collected to obtain a sufficient volume of surficial sediment for the laboratory analysis. Each grab sample was examined for acceptability based on the following criteria:

- The sampler was fully closed.
- There was adequate penetration depth (i.e., sediment volume greater than 25% full).
- The sample did not appear overfilled or disturbed, and the sample did not appear to have been collected on an angle.
- The sampler did not appear to be leaking sediment at a substantial rate (i.e., the top of the sediment profile did not appear to be sloping inwards).

Upon acceptance, the top 5 cm of sediment from the grab sample was removed from the center of the grab using a stainless-steel spoon and transferred to a stainless-steel bowl. The sediment sample was homogenized, and aliquots of the homogenized sample was transferred to clean, laboratory supplied sampling containers. All samples were kept cold until they were shipped on ice in coolers to ALS for analysis of particle size, moisture, total organic carbon (TOC), total metals, benzene, toluene, ethylbenzene, and xylene (BTEX), hydrocarbons (F1-F4), and polycyclic aromatic hydrocarbons (PAHs).

3.2 Data Analysis

Sediment quality data collected at KLK-23 was screened against applicable CCME sediment quality guidelines (SQG) for the protection of marine aquatic life (CCME 1999, CCME 2002). Specifically, data were screened against Probable Effect Levels (PELs) and Interim Sediment Quality Guidelines (ISQGs). PELs were intended to represent concentrations above which adverse effects were predicted to occur frequently. By comparison, the ISQGs were intended to represent concentrations above which adverse biological effects may or may not occur (CCME 2002). To provide a screening value to inform the sediment evaluation, in the absence of a CCME guideline, metals and hydrocarbons were compared to British Columbia (BC) Working Sediment Quality Guidelines (WSQG) (British Columbia Ministry of the Environment and Climate Change Strategy [BC MOE] 2021a), and the National Oceanic and Atmospheric Administration (NOAA) sediment benchmarks (Buchman 2008). The sediment sample from Koluktoo Bay was also qualitatively compared against sediment samples collected at a similar depth (i.e., 28 – 32 m water depths) during the 2023 MEEMP sampling program. Sediment samples collected at approximately 20-32 m water depth were the most comparable to the reference station sample which was collected at 28.3 m depth.

3.3 Quality Assurance/Quality Control

The laboratory QA/QC reports were reviewed upon receipt to confirm adherence to sample hold times and laboratory DQOs, and that the appropriate QA/QC information had been reported. Additionally, a field duplicate sample was collected at KLK-23.

Laboratory QA/QC reports were reviewed upon receipt to confirm adherence to sample hold times and laboratory data quality objectives (DQOs), and that the appropriate QA/QC information had been reported. Laboratory QA/QC included verification of recommended sample holding times and the analysis of laboratory control samples, laboratory duplicates, and spiked samples to assess precision and accuracy of analytical methods.

One field duplicate was sampled at KLK-23. The field duplicate was sampled as a 'split sample' from the same discrete homogenized grab sample as the 'original' sample and identified as Duplicate B (blind sample). To assess the variability between the field duplicate and original sample, the Relative Percent Difference (RPD) was calculated as follows:

$$RPD = \left(\frac{sample - duplicate}{(sample + duplicate)/2}\right) \times 100$$

In accordance with the BC Field Sampling Manual (BC ENV 2023) and CCME (2016), an RPD value of >50% was used to identify notable differences between original and duplicate samples. Values less than five times the Method Detection Limit (MDL) were not included in the RPD calculations because analytical variability near the MDL is higher and does not provide a reliable measure of variability associated with the collection of field samples.

3.3.1 QA/QC Results

The 2023 sediment quality data for the exploratory reference site sample was considered valid and of acceptable quality to address the objectives stated in Section 1.0, based on the following:

- Chemical analyses on sediment samples were completed within the sample hold time requirements.
- No laboratory qualifiers were reported for the original and duplicate sample; therefore, data reported by the laboratory were considered reliable according to the accredited laboratory QA/QC assessment.
- The relative percent difference (RPD) was below the DQO of 50% in the parent/duplicate pair except for gravel (RPD = 51%); however, the DQO exceedance was marginal and particle size in sediment is inherently variable and is therefore not unexpected. The QA/QC results suggest there was low variability and high precision between the duplicate and parent samples which is consistent with sediment quality.

Overall, the QA/QC results indicate that the sediment quality data collected at the exploratory reference site during the 2023 sampling program are of acceptable quality to address the objectives stated in Section 1.0 (Table 7A-2).

3.4 Results and Discussion

Sediments in Koluktoo Bay were primarily composed of sand (70%), gravel (14%), silt (12%), and some clay (4%) (Table 7A- 2). Sand content at the reference station was higher than most shallow MEEMP stations sampled near Milne Port in 2023, and TOC at the reference station was generally lower than the shallow Milne Port stations sampled during the 2023 MEEMP program (i.e., Appendix 3D). Parameter concentrations measured in sediments from Koluktoo Bay were below the applicable CCME sediment quality guidelines (Table 7A- 2). Only barium marginally exceeded the NOAA Apparent Effects Threshold (AET) benchmark by 1.1-times. For parameters without applicable guidelines, aluminum, barium, and strontium were greater than maximum concentrations documented at Milne Port in 2023. PAHs were not detected in the sediment sample similar to the results from the radial transect 2023 program in Milne Port.

Reconnaissance sampling in the reference area indicated that sediment quality in Koluktoo Bay was comparable to Milne Port, reflecting the natural minerology of the area.

Table 7A-2 Sediment Quality Laboratory Results in Koluktoo Bay, 2023

4.0 FISH HEALTH

Fish were collected on 1, 8, and 12 August 2023 in Koluktoo Bay as part of the reference area reconnaissance program for the fish health and tissue chemistry component of the MEEMP. Fishing effort targeted Fourhorn Sculpin (*Myoxocephalus quadricornis*), with Shorthorn Sculpin (*Myoxocephalus scorpius*) collected as an alternate species, in the event catches of Fourhorn Sculpin were insufficient to support the program. This work was completed concurrently with the 2023 MEEMP field program for the Milne Port.

4.1 Sampling Methods

Fishing effort included both active (i.e., angling with 3 rods) and passive (i.e., gill netting with a 91.44 m net) capture methods. Captured fish were enumerated and measured for length and weight. Fourhorn Sculpin were retained for fish health sampling. Shorthorn Sculpin were also retained for fish health assessment as a potential sentinel fish species in future programs. Fish health data for Shorthorn Sculpin were not analyzed herein but the data are provided in Attachment 7A-1. All other fish species were released back into the area they were captured. Fish processing methods were consistent with those described in Section 7.3.1 in Chapter 7.0 – Fish Health and Tissue Chemistry. Tissue samples and aging structures for Fourhorn Sculpin were submitted for tissue chemistry analysis and aging, while samples from Shorthorn Sculpin were archived.

H. arctica sampling was attempted in Koluktoo Bay using a Van Veen (0.1 m^2) grab sampler, following methods described in Chapter 4.0, however, no *H. arctica* specimens were captured during sampling.

4.2 Data Analysis

Fish health data analysis was completed following the methods described in Section 7.3.3 of Chapter 7.0 – Fish Health and Tissue Chemistry. Briefly, descriptive statistics (i.e., sample size, mean, median, standard deviation [SD], standard error [SE], minimum, and maximum values) were calculated for Fourhorn Sculpin fish health endpoints. These indices included condition factor, liver somatic index, and gonadosomatic index.

Fish health indices for Fourhorn Sculpin and Shorthorn Sculpin were calculated as follows:

$$Condition\ factor = \left(\frac{total\ weight}{total\ length^3}\right) \times 100{,}000$$

Additional fish health indices calculated for Fourhorn Sculpin and Shorthorn sculpin were as follows:

$$Gonadosomatic\ index\ (GSI) = \left(\frac{gonad\ weight}{total\ weight}\right) \times 100$$

$$Liver\ somatic\ index\ (LSI) = \left(\frac{liver\ weight}{total\ weight}\right) \times 100$$

Catch-Per-unit-effort (CPUE) was calculated in a standardized way for comparisons amongst sampling effort. CPUE was calculated consistently with the 2023 MEEMP report (Section 6.4.2).

$$Gillnet\ CPUE = \left(\frac{number\ of\ fish}{net\ length \times effort\ hour}\right) \times 100\ m$$

$$Angling\ CPUE = \left(\frac{number\ of\ fish}{number\ of\ rods \times effort\ hour}\right)$$

4.3 Quality Assurance/Quality Control

The same field practices and operations used for the 2023 MEEMP field program, detailed in Section 7.3.2 of Chapter 7.0, were implemented for the fishing effort in Koluktoo Bay. Field and laboratory QA/QC procedures were implemented at each stage of the fish survey, including sampling, data entry, sample shipment, data analyses, laboratory analyses, and report preparation, to produce technically sound and scientifically defensible results.

4.4 Results and Discussion

4.4.1 Habitat

During the reconnaissance survey, similarities in habitat were observed between Milne Port and Koluktoo Bay. Milne Port is in a relatively sheltered area in the southernmost portion of Milne Inlet, where Fourhorn Sculpin habitat is relatively deep (ranging from 0 to more than 10 m) and has a steep slope prior to dropping off to deeper waters. Substrates around the Milne Port are composed nearly entirely boulders with some cobbles. Koluktoo Bay fish sampling and habitat evaluation occurred primarily along the northern shore of the bay, near the Robertson River in a relatively sheltered portion of the bay, similar to Milne Port. Habitat surveyed in this area was relatively deep (ranging from 0.5 m to 8.0 m) and composed primarily of cobbles and boulders that sloped gradually into deeper waters. Shorelines and littoral habitats were generally cobbles with some patches of boulders.

4.4.2 Fish Capture Data

A total of 133 fish were captured from Koluktoo Bay, including 42 Arctic Char (*Salvelinus alpinus*), 36 Shorthorn Sculpin, 31 Fourhorn Sculpin, six Arctic Sculpin (*Myoxocephalus scorpioides*), two Pacific Cod (*Gadus macrocephalus*[1]*),* and one indeterminate sculpin species (*Myoxocephalus* sp.; Table 7A-3). Of the 31 Fourhorn Sculpin captured in Koluktoo Bay, six fish were mortalities (Appendix 6B), and 25 fish were processed for fish health endpoints. Summary statistics for Fourhorn Sculpin processed from Koluktoo Bay are provided in Table 7A- 4.

Fourhorn Sculpin CPUE in Koluktoo Bay was lower than in Milne Port (Table 7A-3). Gill netting was less successful in capturing Fourhorn Sculpin in Koluktoo Bay compared to Milne Port (CPUE: 1.87 versus 5.66 fish/h·100 m, respectively), and Koluktoo Bay had 66% gill netting bycatch to Milne Port's 18%. Angling in Koluktoo Bay was less successful in targeting Fourhorn Sculpin relative to Milne Port (CPUE: 0.27 fish/h*rod versus 4.86 fish/h*rod), and Koluktoo Bay had 93.8% bycatch to Milne Port's 27.5%.

[1] Recent taxonomic changes to the genus *Gadus* have combined species *G. ogac* (Greenland Cod) and *G. macrocephalus* (Pacific or Alaska Cod) under the umbrella term *G. macrocephalus* (FishBase 2023; GBIF 2023). A universal edit has been made to change Greenland cod (*G. ogac*) to Pacific Cod (*G. macrocephalus*).

Table 7A- 3: Total Catch Per Unit Effort for Fish Captured from Koluktoo Bay Reference Area Reconnaissance Surveys, 2023.

Site	Angling – Jigging				Gill Nets			
	Effort (h*rod)	Species	# of Fish Captured	CPUE (fish/h·rod)	Effort (h·100 m)	Species	# of Fish Captured	CPUE (fish/h·100 m)
Koluktoo Bay	7.35	ARCH	0	0	15.5	ARCH	42	2.72
		FHSC	2	0.27		FHSC	29	1.87
		SHSC	25	3.40		SHSC	11	0.71
		ARSC	2	0.27		ARSC	4	0.26
		GRCD	2	0.27		GRCD	0	0
		Sculpin sp.	1	0.14		Sculpin sp.	0	0
Milne Port	10.75	ARCH	1	0.09	39.3	ARCH	48	1.22
		FHSC	50	4.65		FHSC	223	5.66
		SHSC	12	1.12		SHSC	1	0.03
		ARSC	0	0		ARSC	1	0.03
		GRCD	6	0.56		GRCD	0	0
		Sculpin sp.	0	0		Sculpin sp.	0	0

ARCH = Arctic Char; ARSC = Arctic Sculpin; FHSC = Fourhorn Sculpin; GRCD = Pacific Cod (previously Greenland Cod); SHSC = Shorthorn Sculpin; CPUE = Catch per unit effort; m = meter; # = number; h = hour; nd = no data.

CPUE calculated as an index of total abundance (Section 6.5.1, Chapter 6).

Koluktoo Bay likely contains a sufficiently large population of Fourhorn Sculpin to support target sample sizes for the MEEMP fish health program. However, due to high bycatch numbers for both capture methods at Koluktoo Bay and the potential for mortalities of bycatch, sampling in another area in Koluktoo Bay may be investigated. The southern portion of Koluktoo bay (17X 497720E 7994082N) appears to reflect similar conditions to Milne Port. Milne Port is in a sheltered southwestern bay and imagery of the southern portion of Koluktoo Bay shoreline appears similar to Milne port.

While CPUE for gillnetting in Koluktoo Bay was greater than 1.0 fish/h·100 m, it can be a destructive fishing method, resulting in damage and risk of mortalities to bycatch and target species. Alternative fishing methods such as hoop nets may be considered in supporting future monitoring programs to limit bycatch and unnecessary mortalities, with additional angling effort (i.e., more time, additional fishers) expended to achieve target sample sizes for Fourhorn Sculpin.

Given the presence and the demonstrated catchability of Fourhorn Sculpin in Koluktoo Bay, this area likely represents a reasonable candidate for a reference area for the MEEMP fish health and tissue chemistry program.

5.0 CONCLUSIONS

Supporting water and sediment quality data collected within Koluktoo Bay in 2023 suggest the area is broadly comparable to Milne Port in terms of water and sediment chemistry. Fourhorn Sculpin numbers in Koluktoo Bay appeared adequate to support sample size requirements for the MEEMP fish health and tissue chemistry program, indicating the area may be an appropriate reference area to support the MEEMP. Additional sample collections are recommended in 2024 from Koluktoo Bay to confirm the presence, abundance, and catchability of Fourhorn Sculpin in the area, and to allow refinement of fishing methods to limit bycatch. Additional effort should be expended in 2024 to more broadly confirm the supporting chemistry (i.e., water, sediment) results of the 2023 reference area reconnaissance survey through the addition of more reference area sampling stations for supporting chemistry.

6.0 CLOSURE

We trust this information is sufficient for your needs at this time. Should you have any questions or concerns, please do not hesitate to contact Phil Rouget, on behalf of the undersigned, at +1 250 419 4945.

Table 7A-A3: Fish Survey Assessment Codes

Variable	Variable Condition	Original Field Designation
Body deformity	Normal	N
	Spinal deformity - Other	X
Eyes	No aberrations; good “clear” eye	N
	Blind; an opaque eye (one or both)	B
	Swollen, protruding eye (one or both)	E
	Hemorrhaging or bleeding in the eye (one or both)	H
	Missing one or both eyes	M
	Other; any manifestation not fitting the above	OT
Thymus	No hemorrhage	0
	Mild hemorrhage	1
	Moderate hemorrhage	2
	Severe hemorrhage	3
Skin	Normal; no aberrations	0
	Mild skin aberrations	1
	Moderate skin aberrations	2
	Severe skin aberrations	3
Fins	No active erosion	0
	Light active erosion	1
	Moderate active erosion with some hemorrhaging	2
	Severe active erosion with hemorrhaging	3
Opercle	No shortening	0
	Mild shortening	1
	Severe shortening	2
Hindgut	Normal; no inflammation or reddening	0
	Slight inflammation or reddening	1
	Moderate inflammation or reddening	2
	Severe inflammation or reddening	3
Parasites	No observed parasites	0
	Few observed parasites	1
	Moderate parasite infestation	2
	Numerous parasites	3

(a) 0 = No observed parasites; 1 = Few observed parasites; 2 = Several observed parasites; 3 = Many observed parasites.

(b) A = Normal, solid red or light red colour; C = "Fatty" liver, "coffee with cream" colour.

% = percent; N, 0, or B = normal; - = not collected; < = less than

Table 7B-3: Fish Health Data for *Hiatella arctica* Lethally Sampled from the Milne Port Area and Tugaat River Estuary Reference Area, 2023

Date (dd/mm/yy)	Effort Number	Fish Identification Number	Composite	Field Measurements		Laboratory Measurements[a]								
				Total Length (mm)	Whole Animal Wet Weight (g)	Total Length (mm)	Total Height (mm)	Total Width (mm)	Whole Animal Wet Weight (g)	Shell Wet Weight (g)	Tissue Wet Weight (g)	Gonad Wet Weight (g)	Shell Dry Weight (g)	Age (y)

Notes:

Statistically significant values and magnitudes of effect greater than the CES are indicated in **bold**. Statistical outliers are provided in Appendix 7B, Table 7B-12.

(a) For model components, please see Table 7-3 in Chapter 7.

(b) Critical Effect Size (CES) expressed as a percentage of the Koluktoo Bay mean.

(c) Power Analysis values presented on measurement scale. Log_{10}-transformed models include values for differences below and above the Koluktoo Bay mean.

(d) Minimum Detectable Difference expressed as unit difference from the Koluktoo Bay mean.

(e) Sensitivity is the minimum detectable difference expressed as a percent change in the Koluktoo Bay mean.

(f) The R^2 value for the full model was less than the threshold (0.791 < 0.800) for assuming slopes are practically parallel (Barrett et al., 2010). Therefore, size-at-age was compared at the smallest and largest overlapping covariate values among study years, following Section A1.7 in Environment Canada (2012).

n = sample size; LSM = least squares mean; P-value = probability value; log_{10} = log_{10}-transformed data; rank = rank-transformed data; ANOVA = analysis of variance; ANCOVA = analysis of covariance; n/a = not applicable.

Notes:

Statistically significant values are indicated in **bold**. Statistical outliers are provided in Appendix 7B, Table 7B-12.

(a) For model components, please see Table 7-2 in Chapter 7.

(b) log ANCOVA proceeded despite significant interaction term based on visual inspection of the data.

(c) Power Analysis values presented on measurement scale. Log_{10}-transformed models include values for differences below and above the overall mean.

(d) Minimum Detectable Difference expressed as difference from the overall mean.

(e) Sensitivity is the minimum detectable difference expressed as a percent change in the overall mean.

P-value = probability value; log_{10} = log_{10}-transformed data; rank = rank-transformed data; ANOVA = analysis of variance; ANCOVA = analysis of covariance; n/a = not applicable.

Notes:

Statistically significant values are indicated in **bold**. Power analysis was completed assuming normality.

(a) For model components, please see Table 7-4 in Chapter 7.

(b) P-values adjusted using Holm's correction for multiple comparisons (Holm 1979).

(c) ANCOVA completed only in range of overlapping total length between years (>25 mm) following Section A1.7 in Environment Canada (2012). See Figure 7-9 for *H. arctica* length-frequency distributions from 2020, 2021, 2022, and 2023.

(d) ANCOVA completed only in range of overlapping soft tissue weights between years (0.61 to 2.75 g ww) following Section A1.7 in Environment Canada (2012).

(e) Minimum Detectable Difference expressed as unit difference from the Koluktoo Bay mean.

(f) Sensitivity is the minimum detectable difference expressed as a percent change in the overall mean.

(g) Sensitivity is the minimum detectable difference expressed as a percent change in the overall mean.

(h) The R^2 value for the full model was less than the threshold (0.772 < 0.750) for assessing if slopes are practically parallel (Barrett et al., 2010); therefore, mantle somatic index was compared at the smallest and largest overlapping covariate values among study years, following Section A1.7 in Environment Canada (2012).

P-value = probability value; log_{10} = log_{10}-transformed data; K-S Test = Kolmogorov-Smirnov test; ANOVA = analysis of variance; ANCOVA = analysis of covariance; n/a = not applicable.

Table 7B-12: Outliers Omitted from Statistical Comparisons of Fish Health Endpoints, 2020 – 2023

Species	Sex	Parameter	Grouping	FIN	Total Length (mm)	Total Weight (g)	SR
Temporal

Note: Significant differences indicated in **bold**.

(a) Power Analysis values presented on measurement scale. Log_{10}-transformed models include values for differences below and above the grand mean.

(b) Minimum Detectable Difference expressed as difference from the overall mean.

(c) Sensitivity is the minimum detectable difference expressed as a percent change in the overall mean.

(d) Length was included as a covariate for ANCOVA and MLR.

RPD = Relative Percent Difference; ANOVA = analysis of variance; ANCOVA = analysis of covariance; log = log10-transformed data; rank = rank-transformed data; - = not calculated, no data available.

Table 7C-13: Supporting Information for Trend Analysis of Chemicals of Potential Concern in Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Samples Collected from the Milne Port Area from 2018 to 2023.

Note: Significant differences indicated in **bold**.

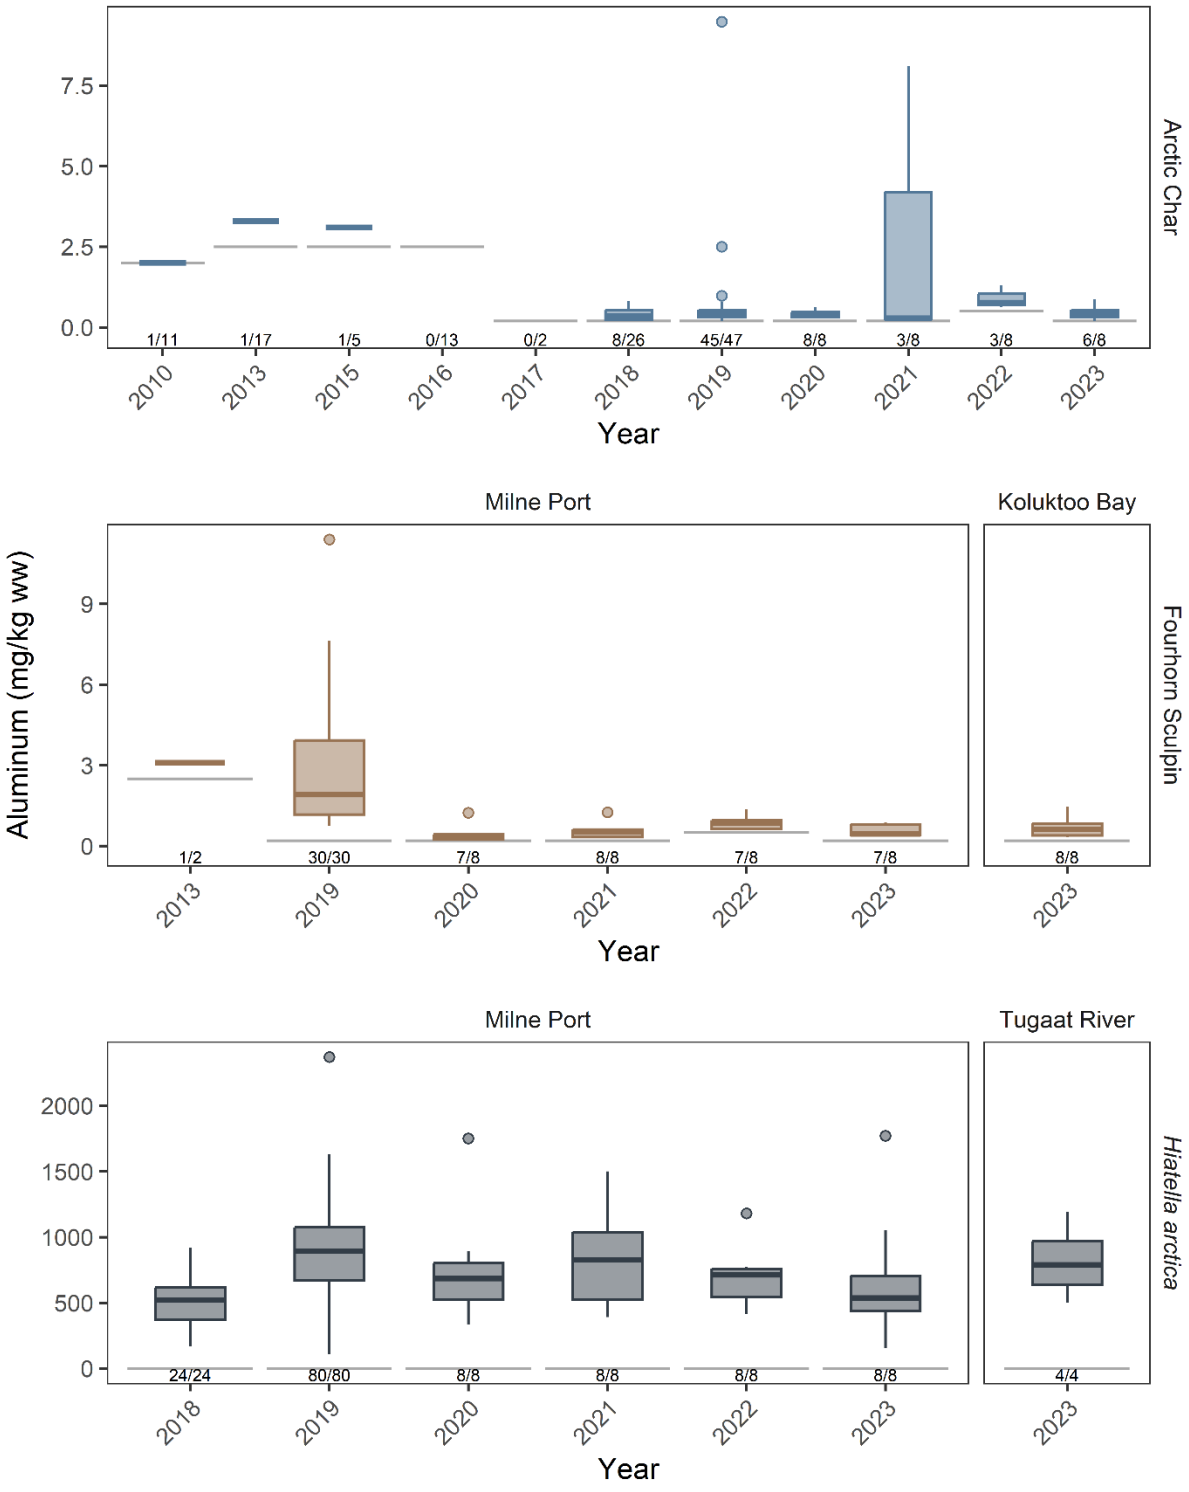
(a) For linear regression models, heteroscedasticity was evaluated with the Breusch-Pagan test. For ANCOVA models, heteroscedasticity was evaluated using Levene's test.

(b) Power Analysis values presented on measurement scale. Log_{10}-transformed models include values for differences below and above the grand mean.

(c) Minimum Detectable Difference expressed as difference from the overall mean on the original measurement scale (i.e., not log-transformed). For rank-transformed variables, difference expressed on the rank-scale.

(d) Sensitivity is the minimum detectable difference expressed as a percent change in the overall mean.

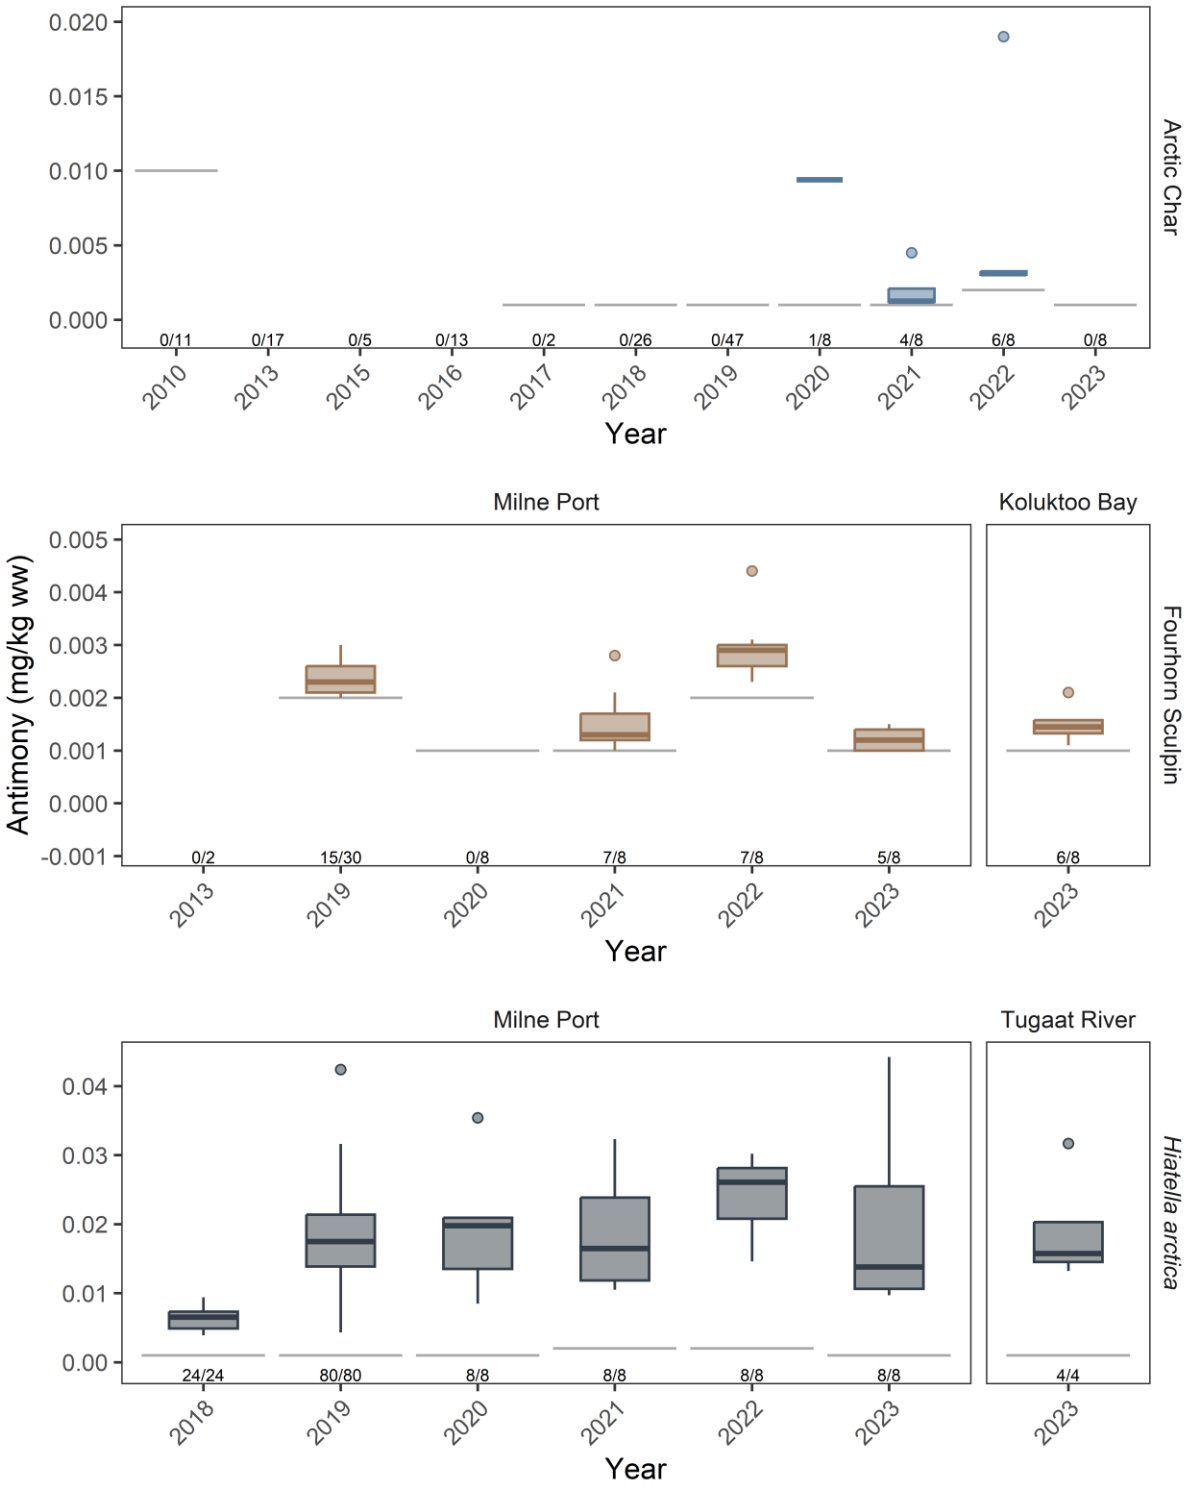
(e) Rank ANCOVA proceeded despite violation of normality. See Section 7.3.4.3.



(f) Length was included as a covariate for ANCOVA and MLR.

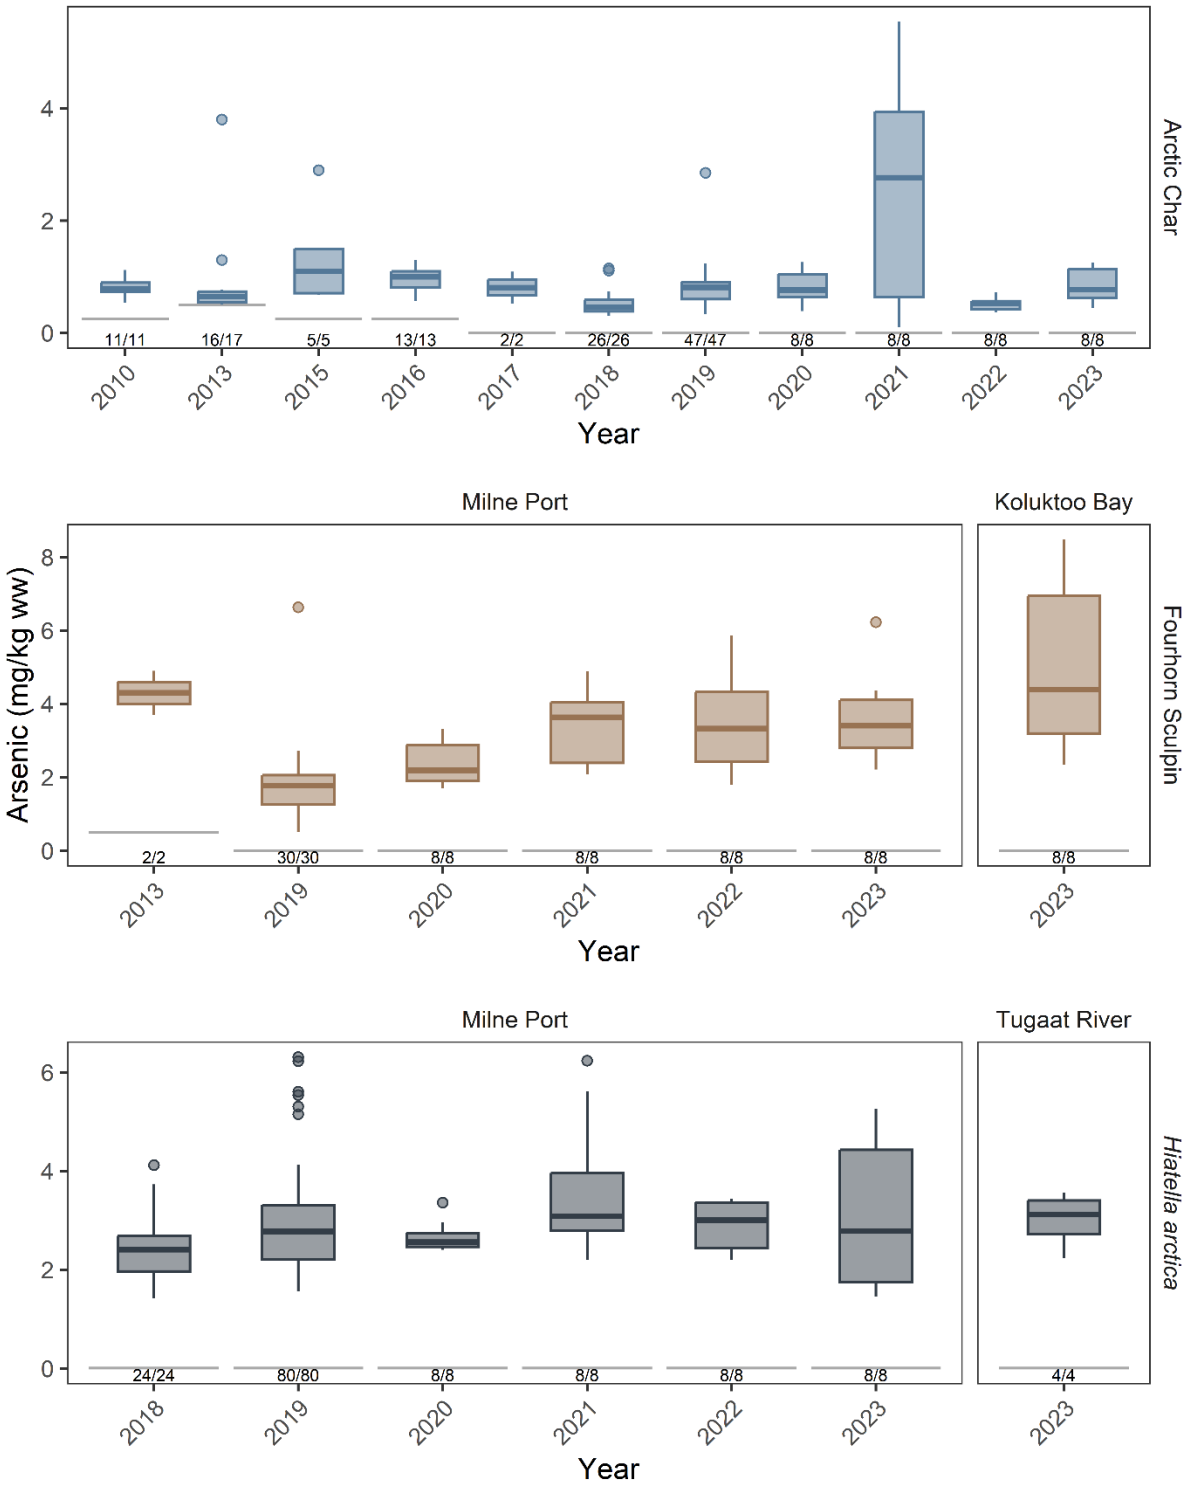
(g) Parameter concentrations were compared at 217 mm length due to narrow range of covariate overlap among sampling years.

LR = linear regression; ANCOVA = analysis of covariance; log = log_{10}-transformed data; rank = rank-transformed data; - = not calculated, no data available.



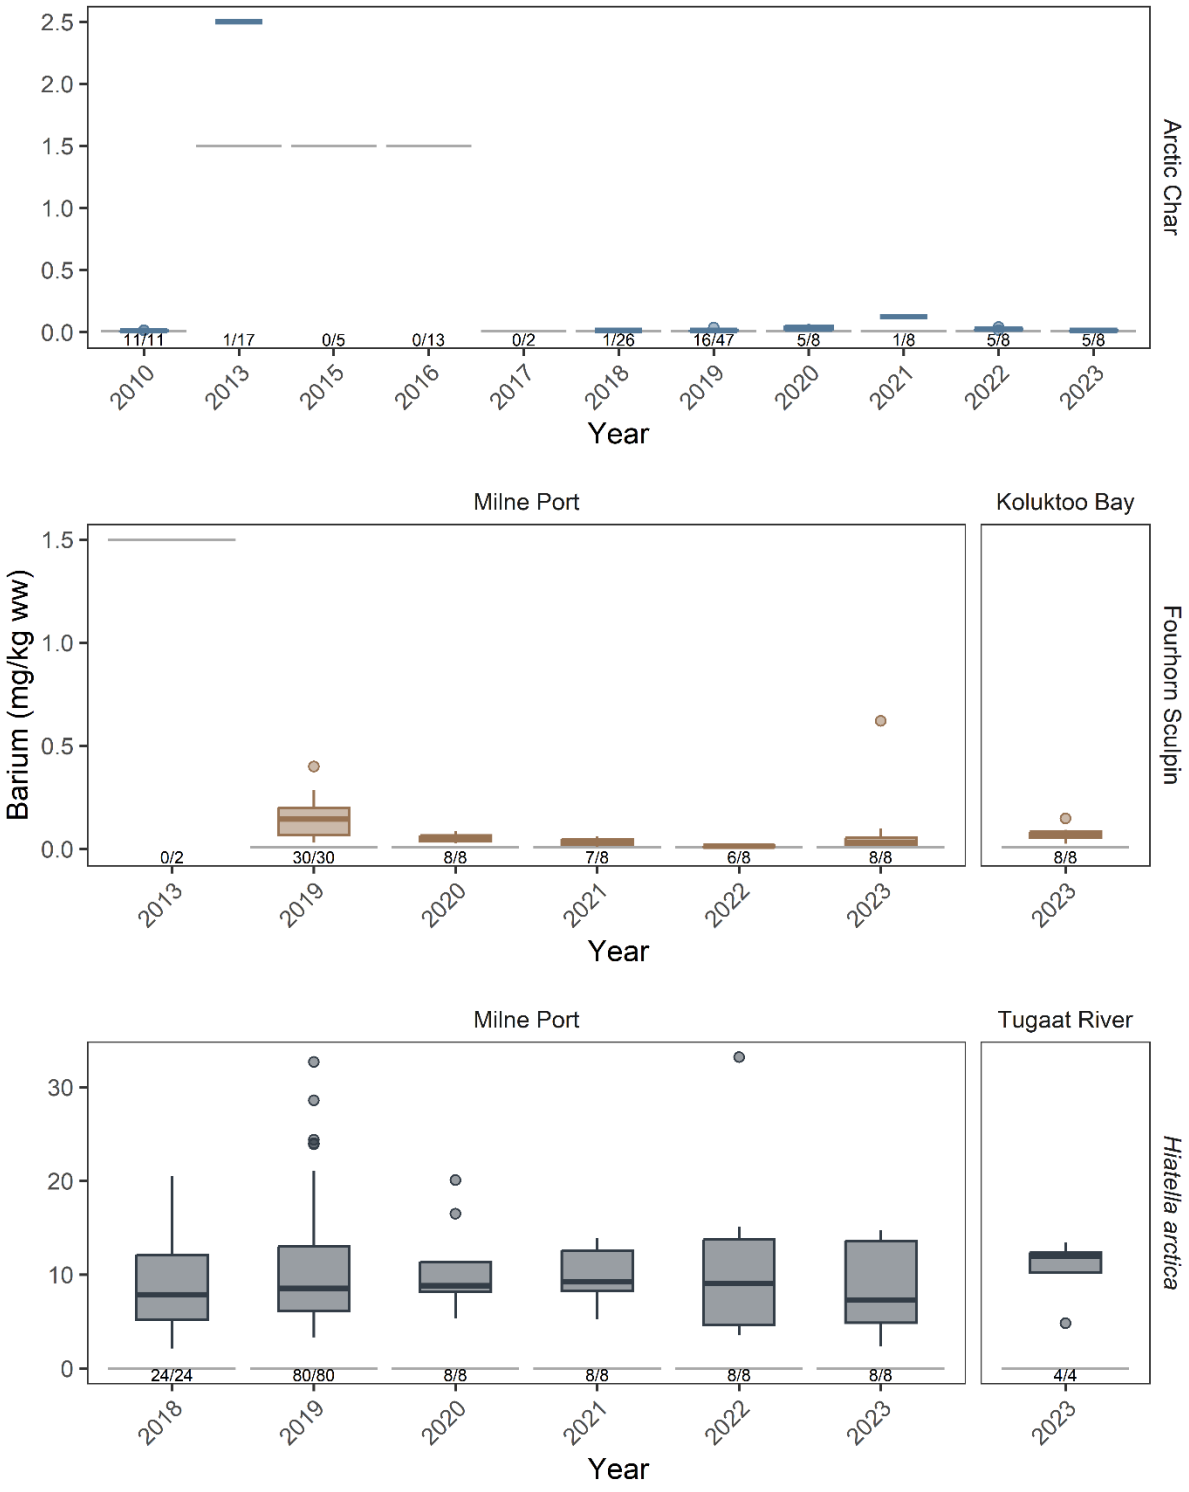
APPENDIX 7D

Fish Tissue Boxplots



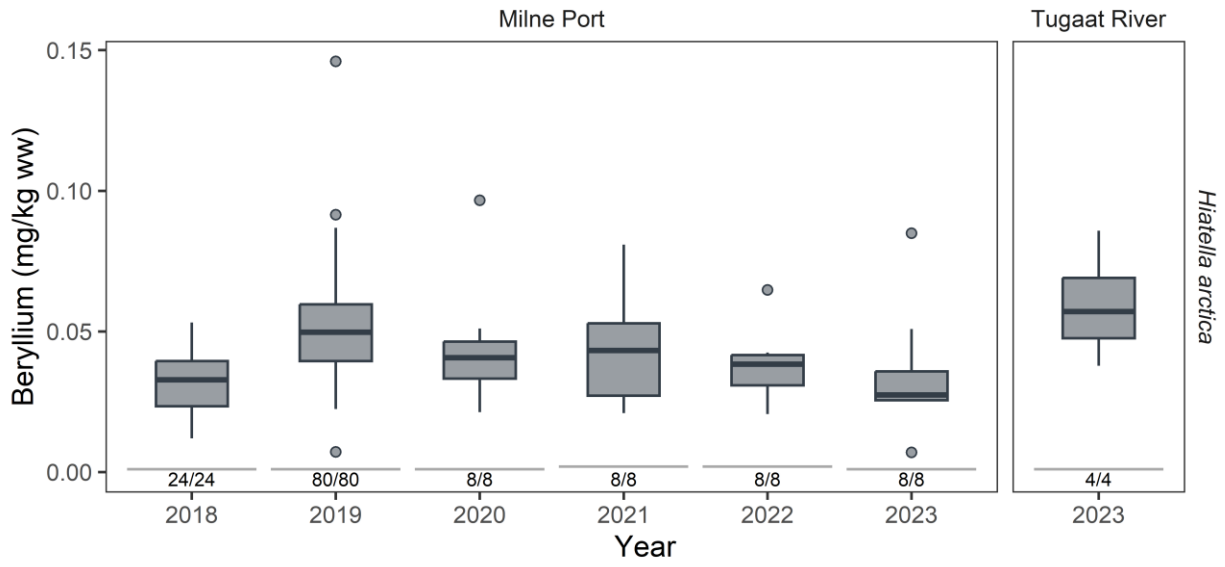
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-1: Concentrations of Aluminum for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



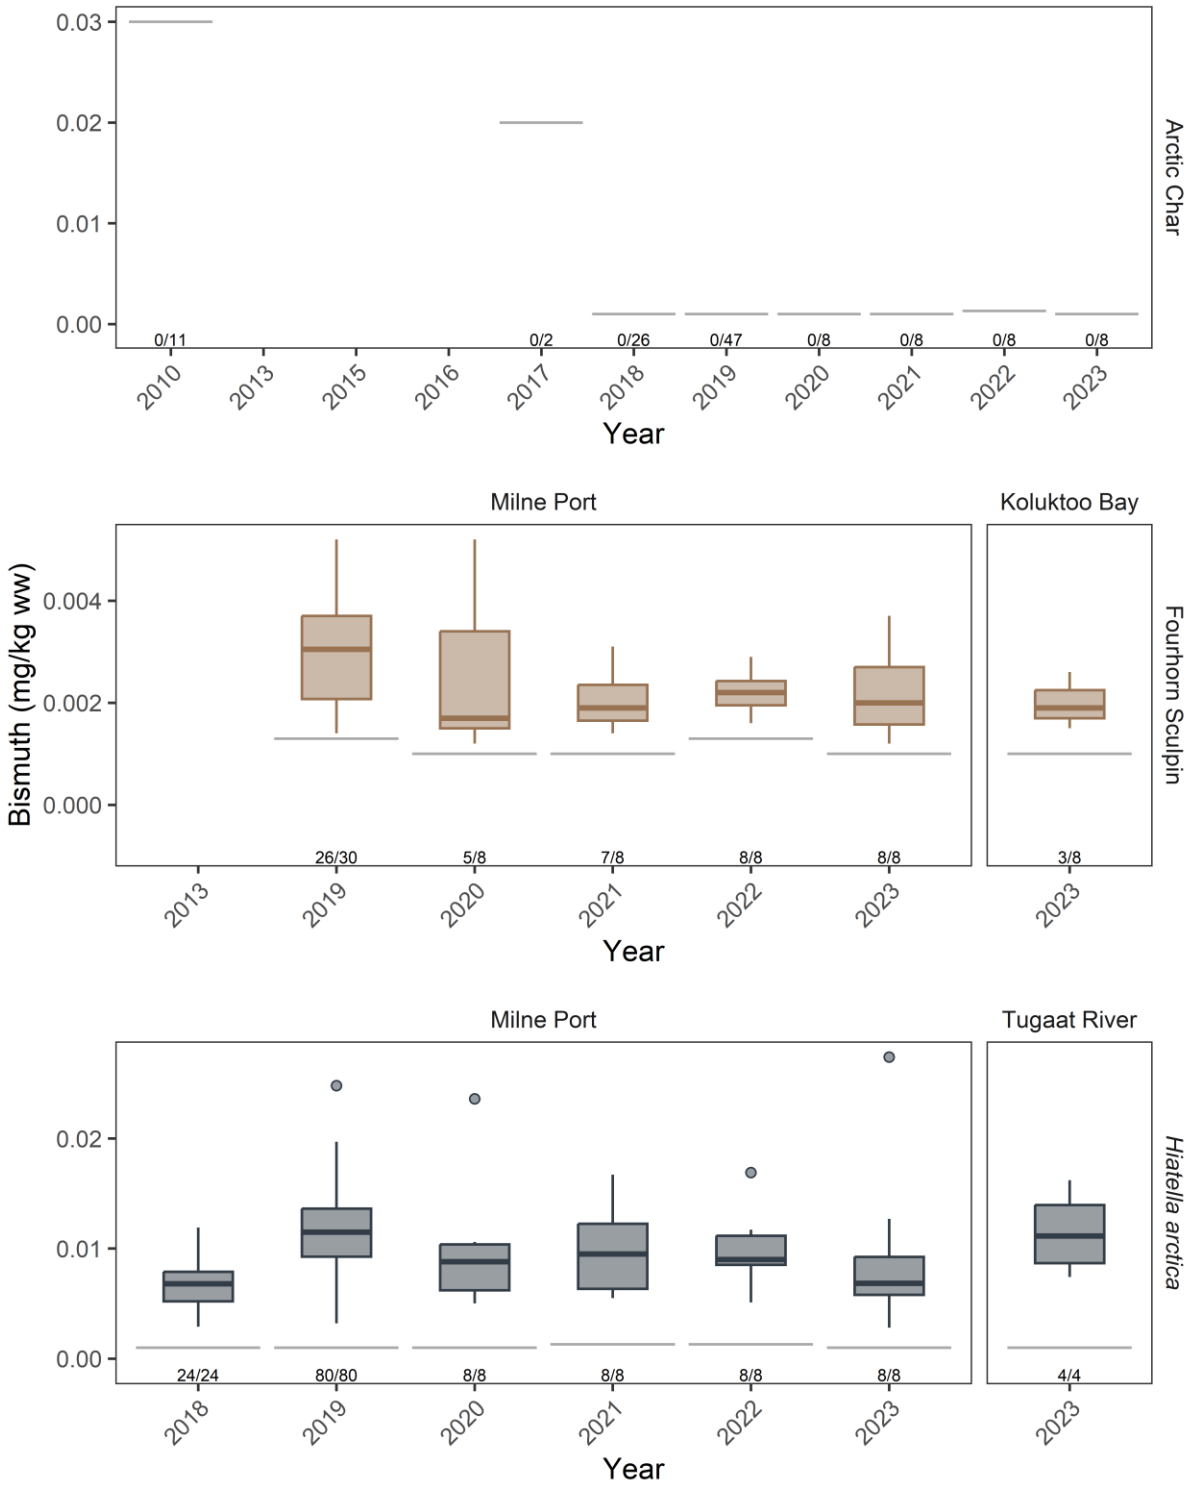
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits. Detection limit of 0.5 mg/kg ww for Arctic Char (2013, 2015, 2016) and Fourhorn Sculpin (2013) not shown to allow for clearer visualization of the data.

Figure 7D-2: Concentrations of Antimony for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



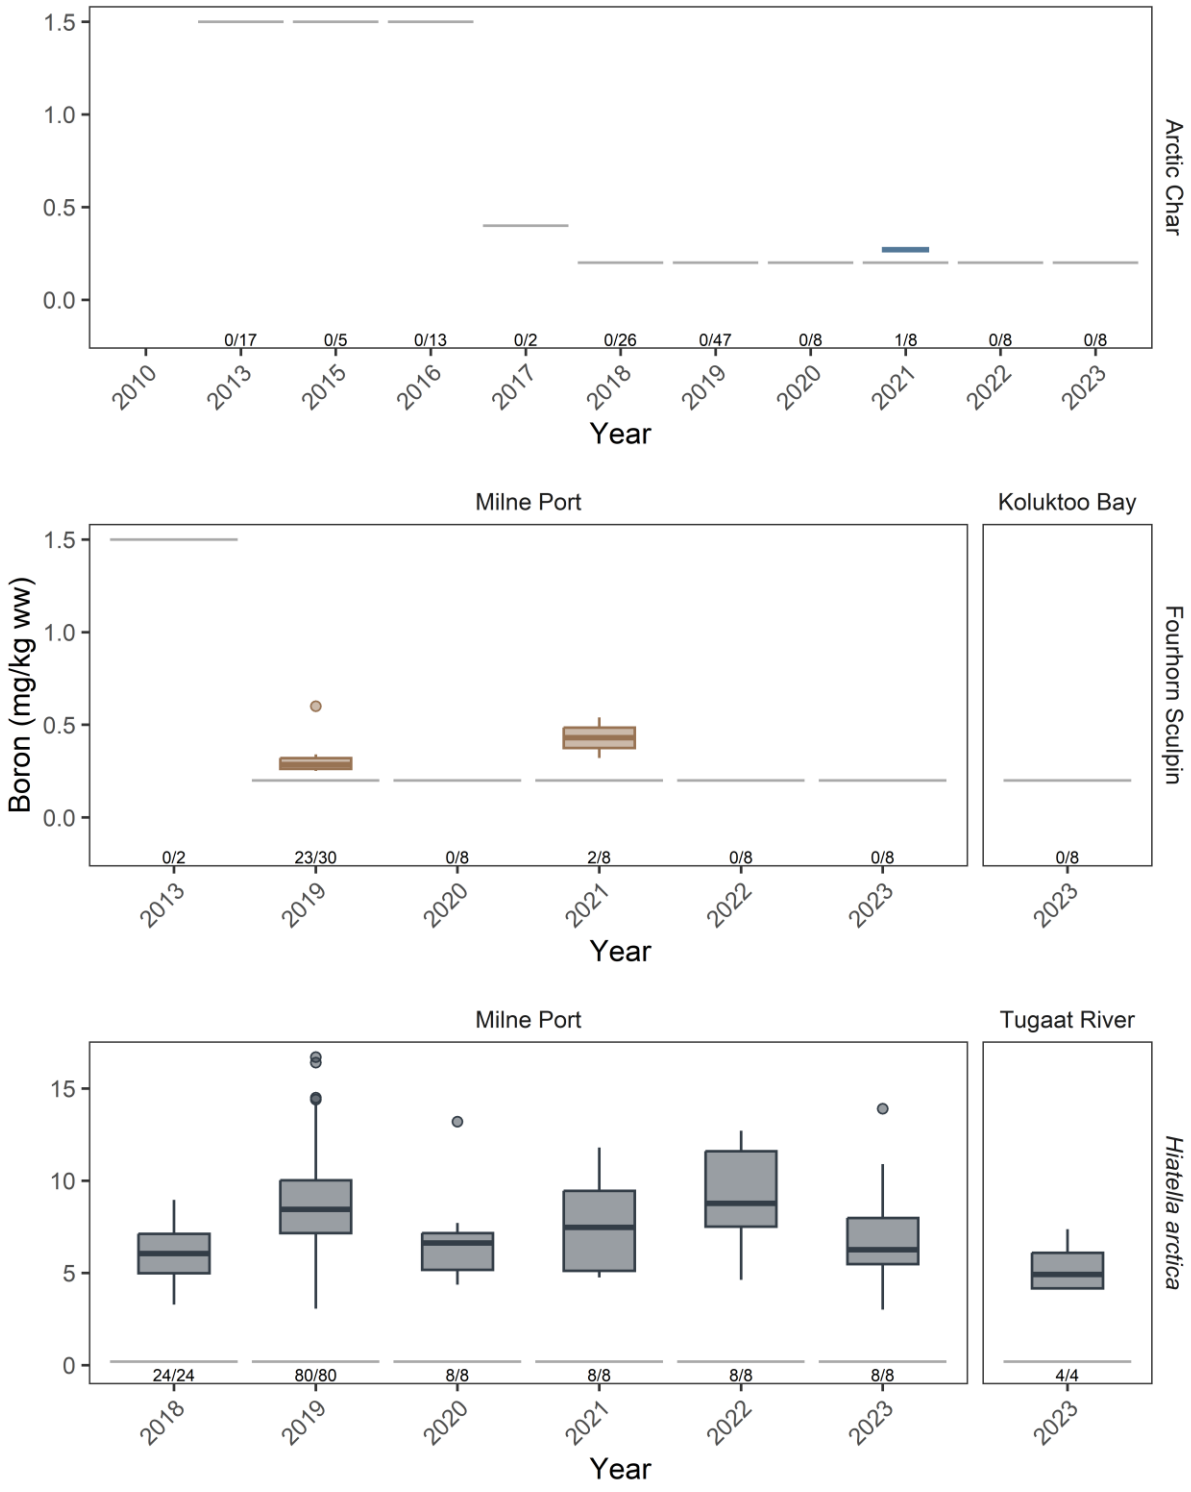
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits. One Arctic Char sample removed from 2020 (BAFF20UMLNGN18ARCH003, 33.2 mg/kg ww) to improve plotting.

Figure 7D-3: Concentrations of Arsenic for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



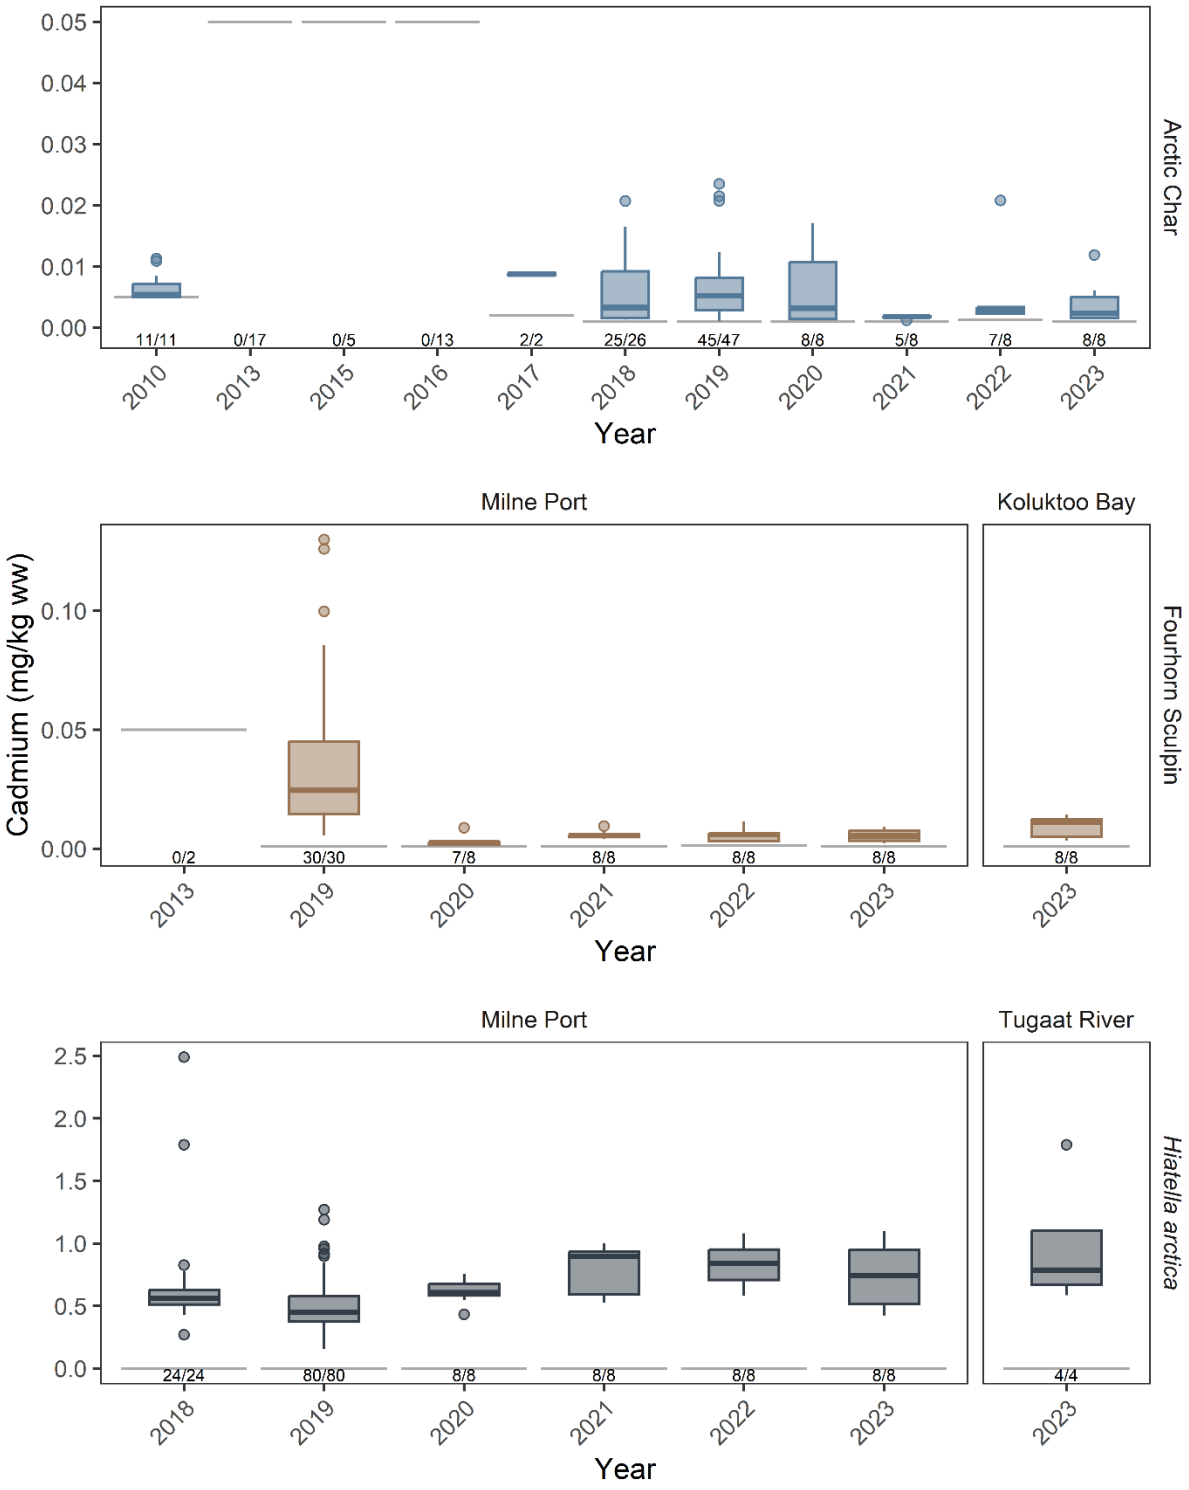
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-4: Concentrations of Barium for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



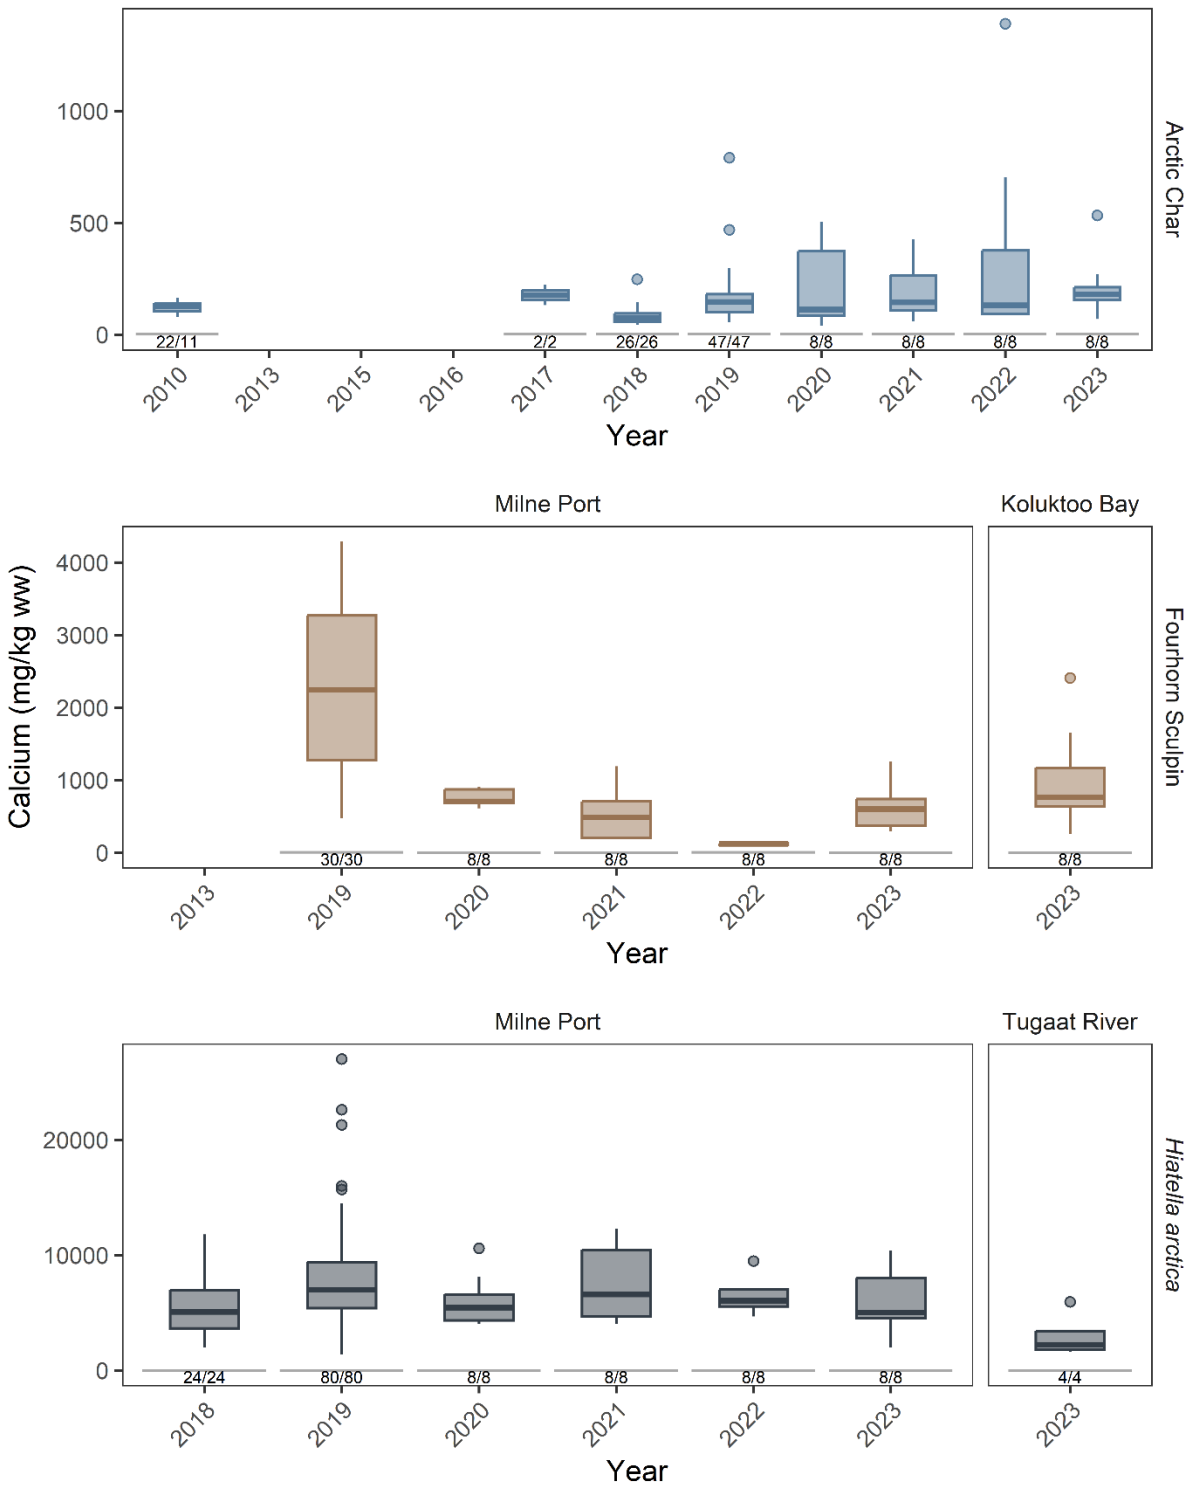
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-5: Concentrations of Beryllium for *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



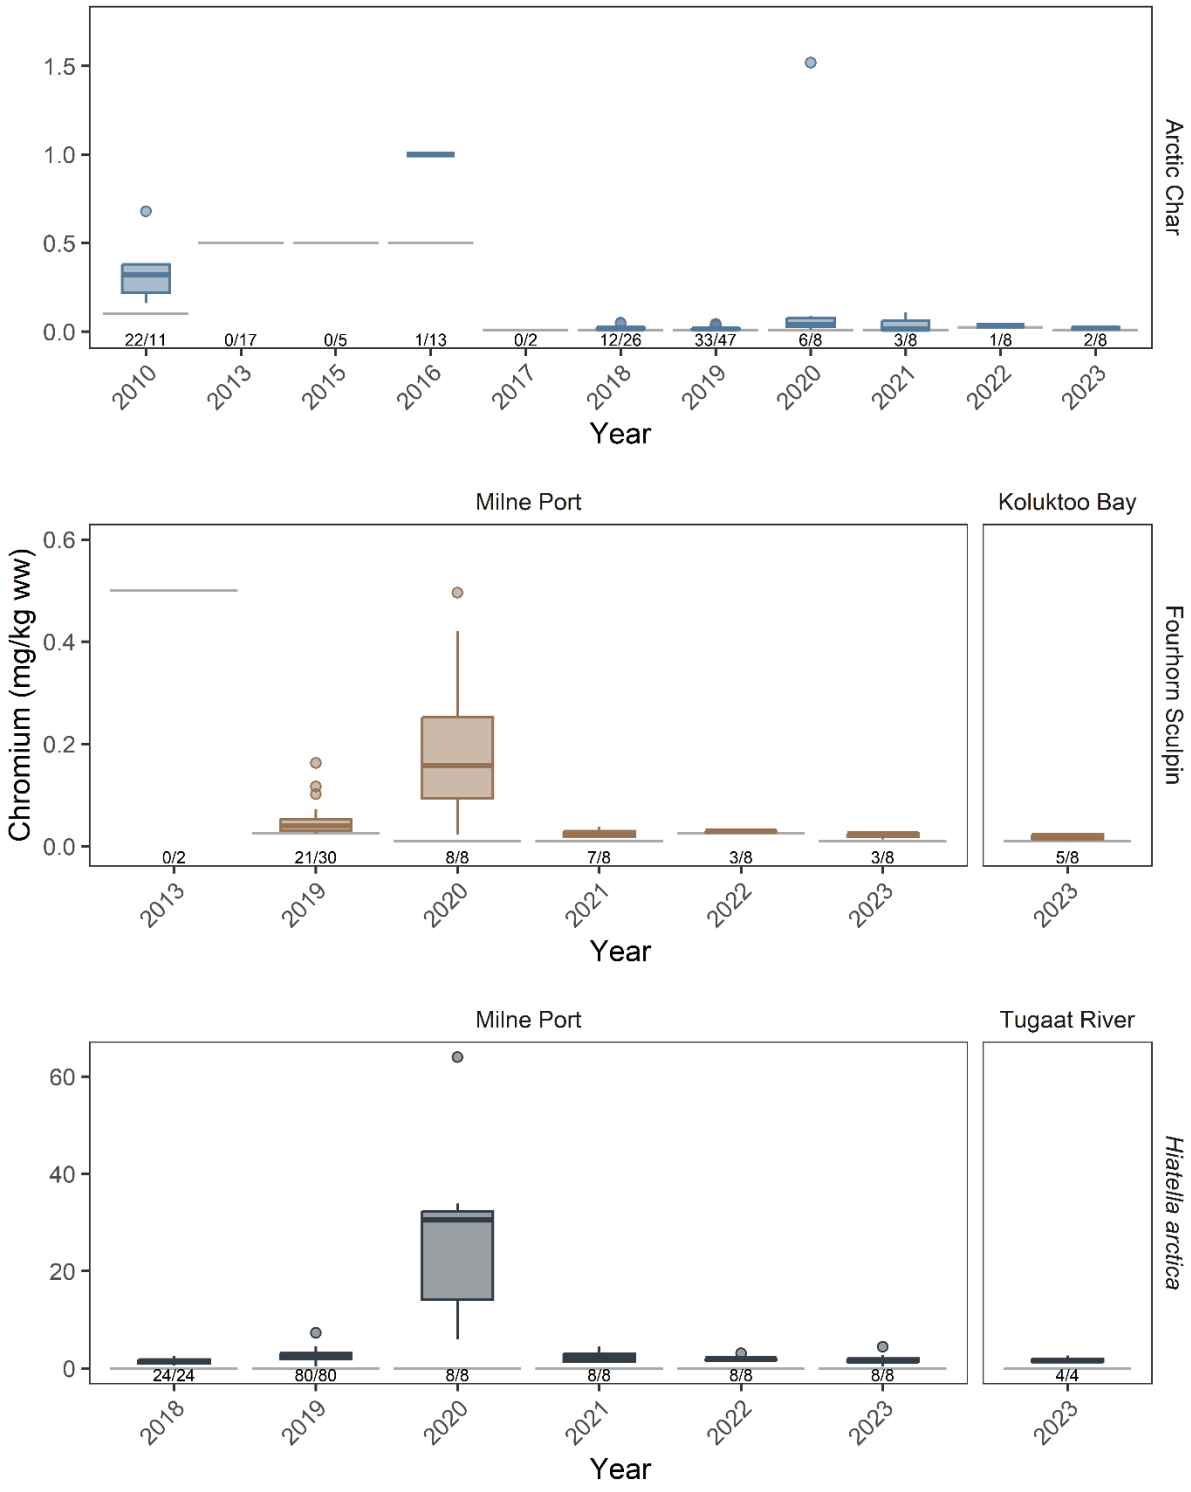
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-6: Concentrations of Bismuth for Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



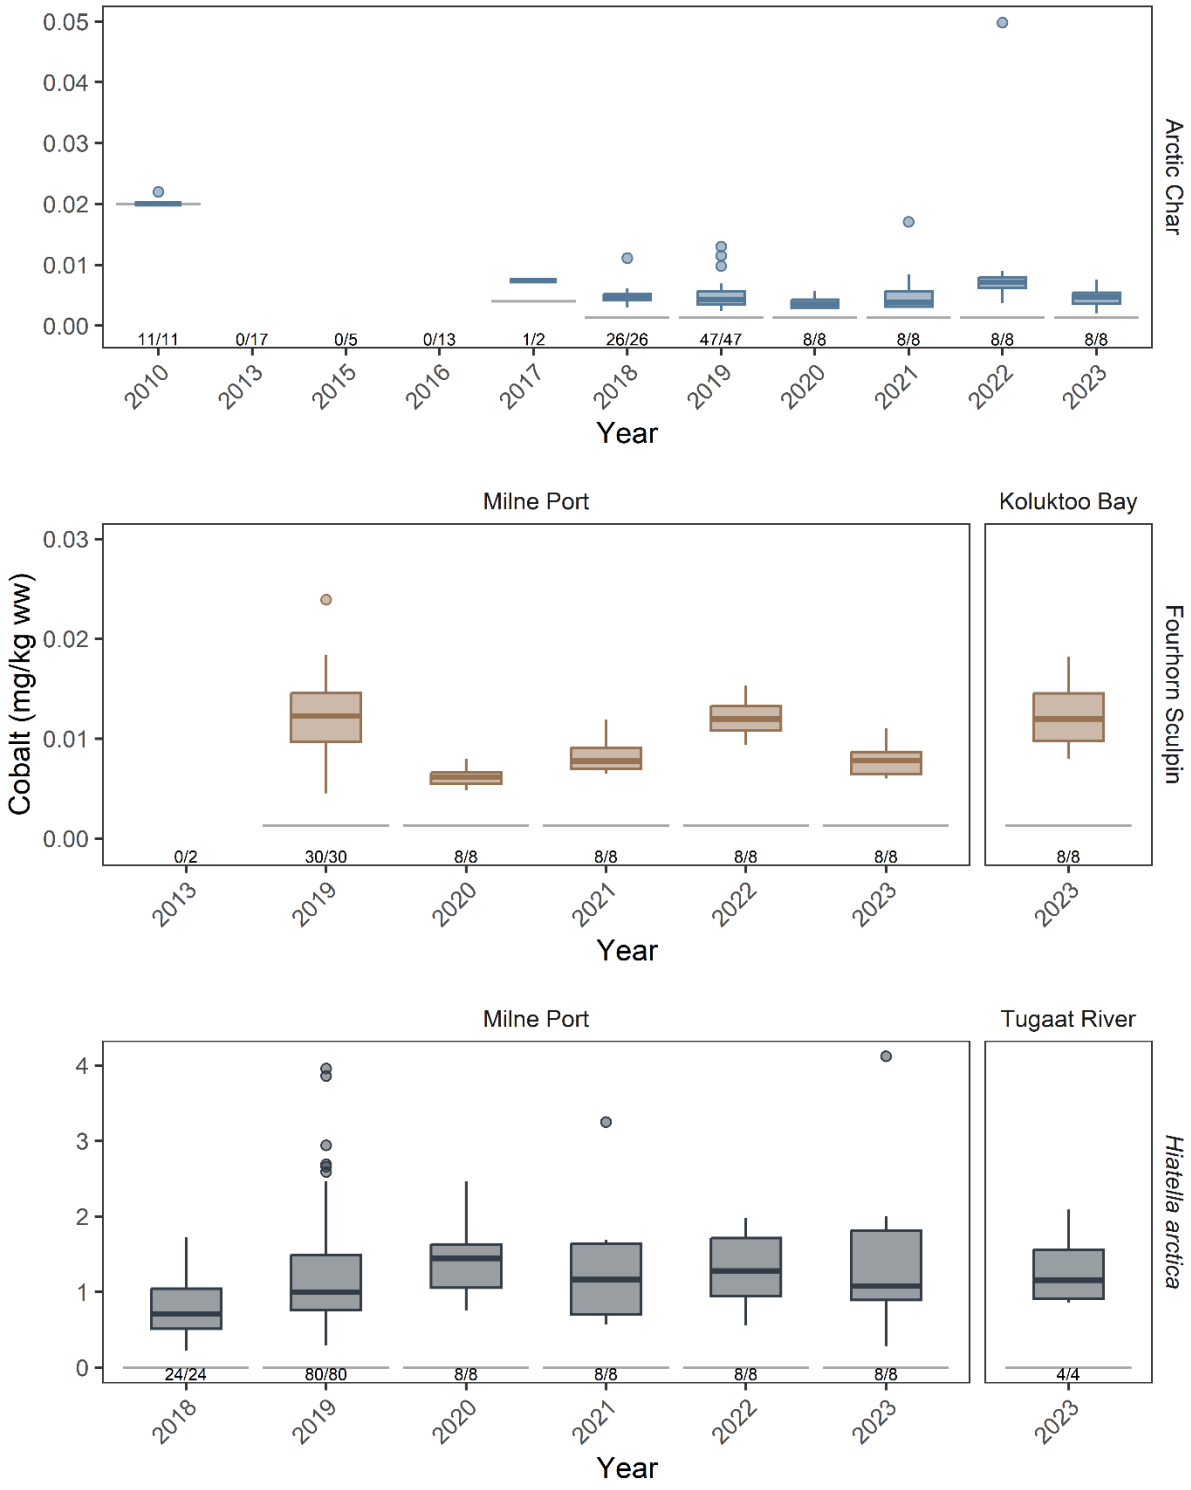
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-7: Concentrations of Boron for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



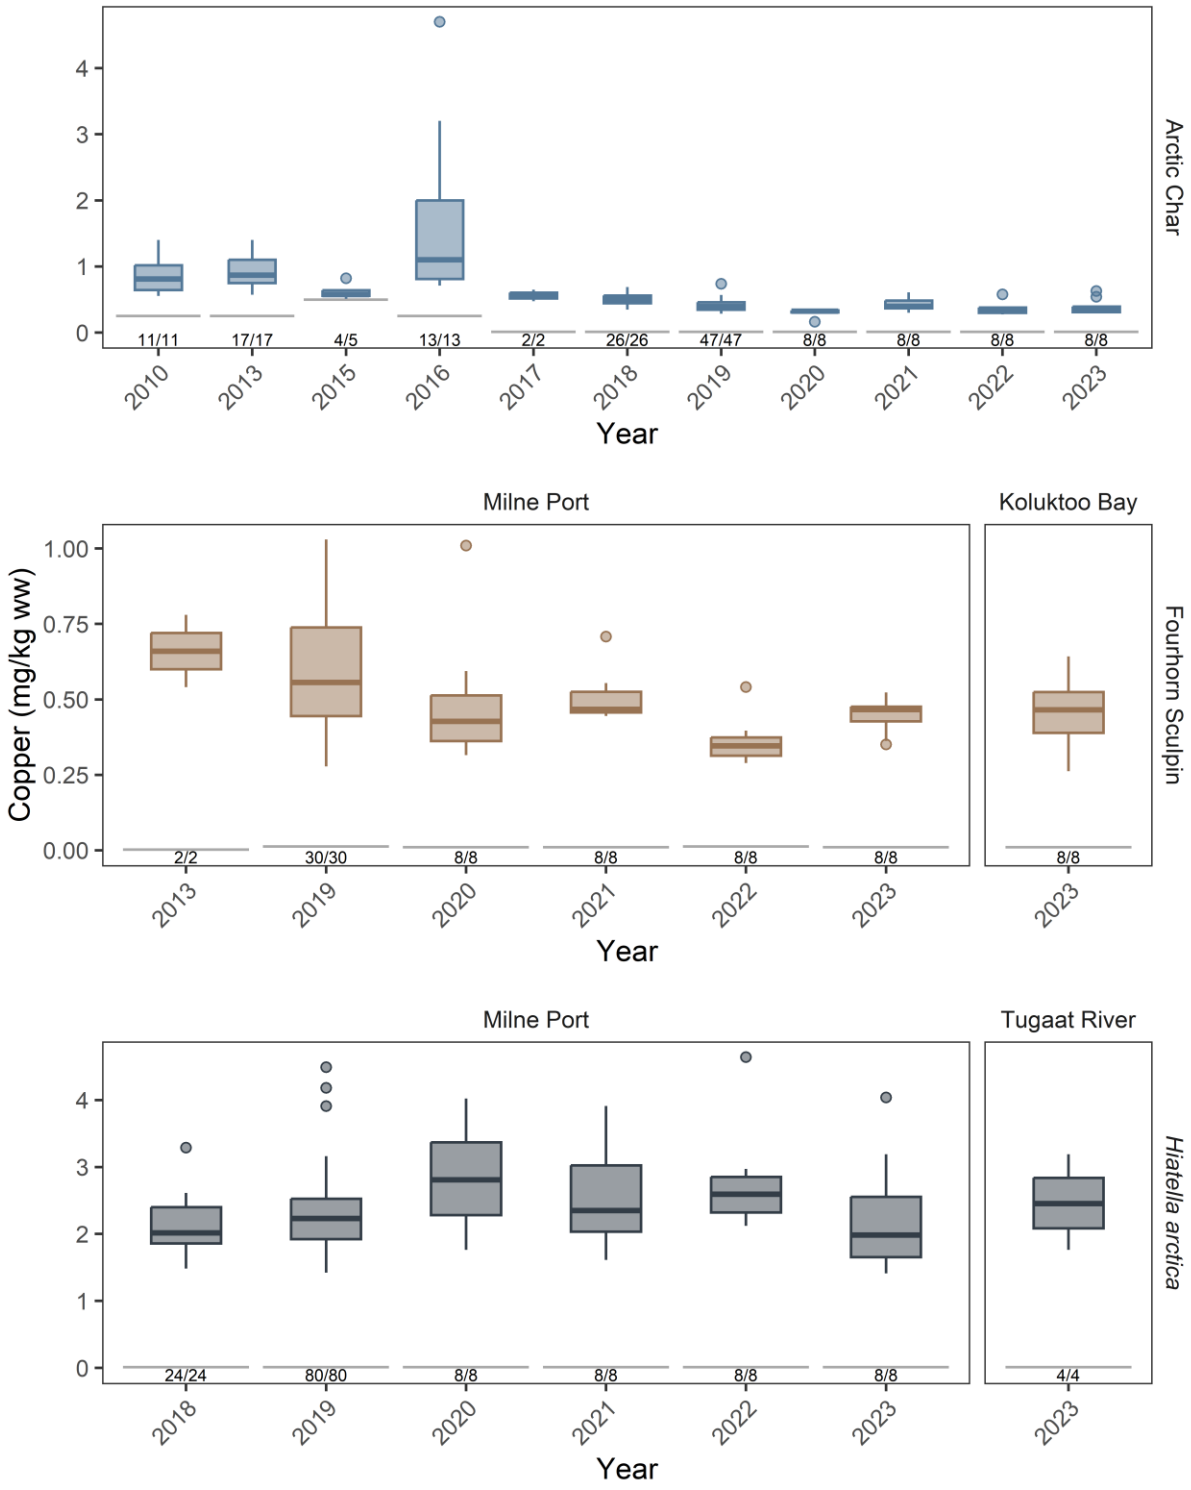
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-8: Concentrations of Cadmium for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



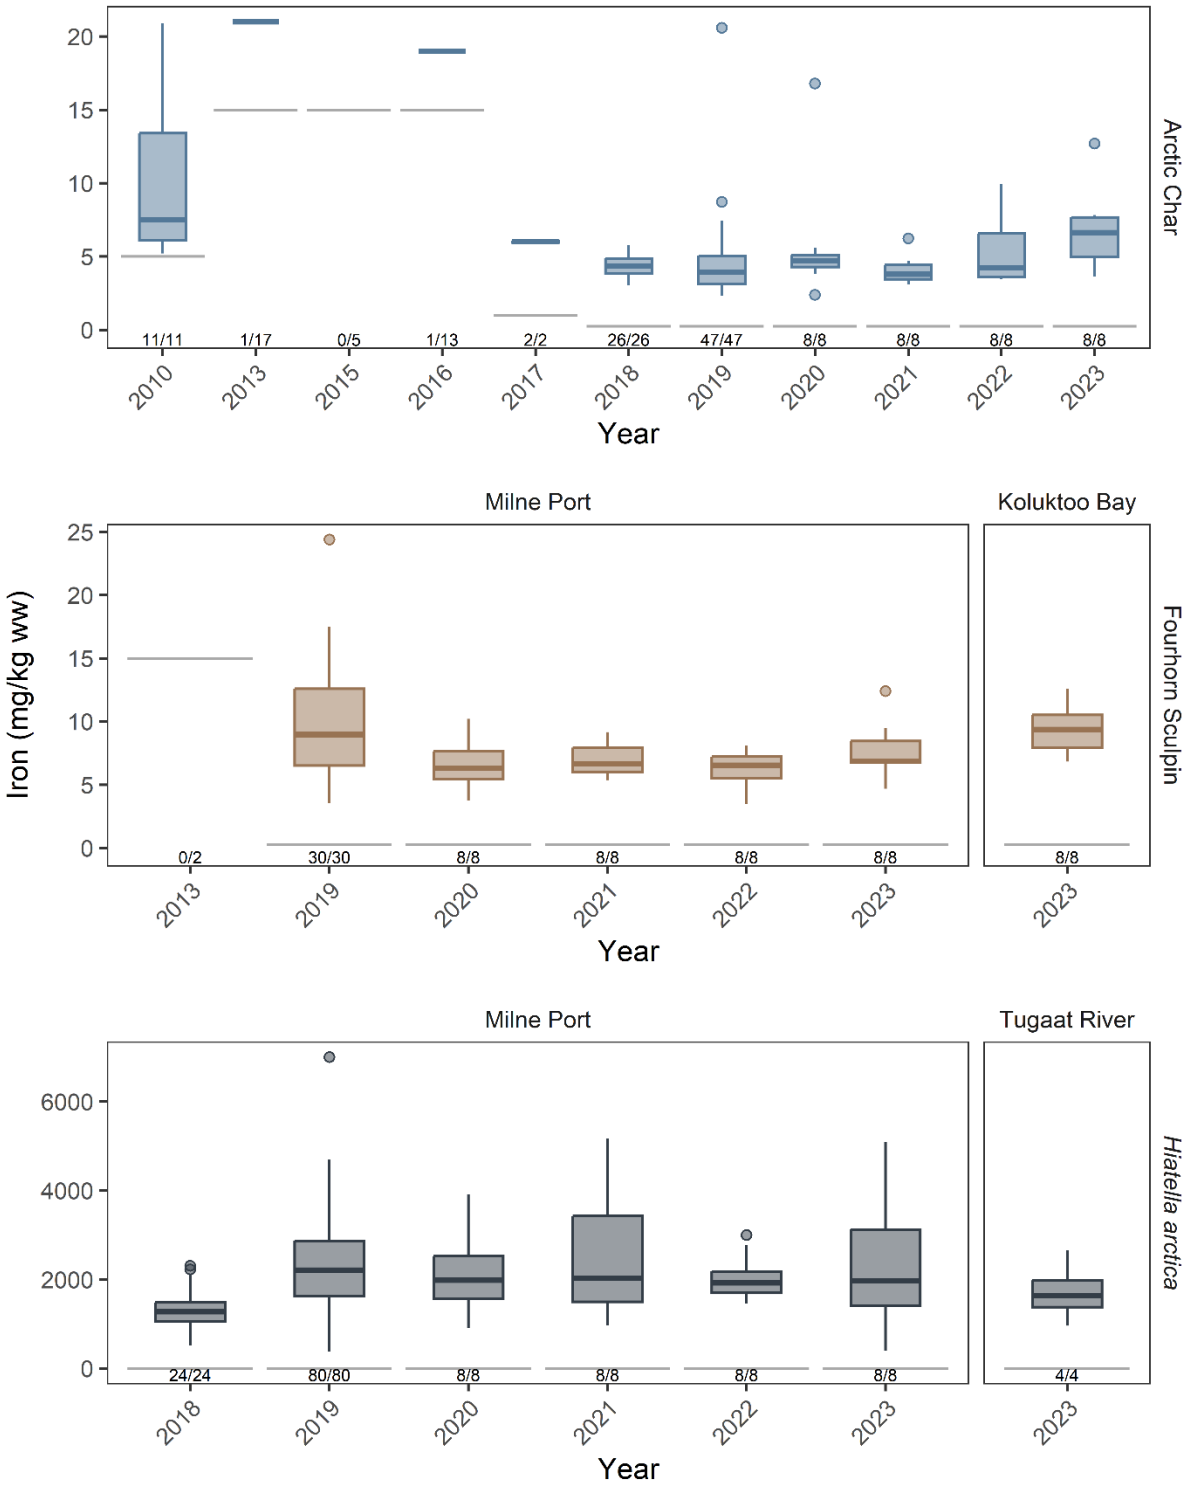
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-9: Concentrations of Calcium for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



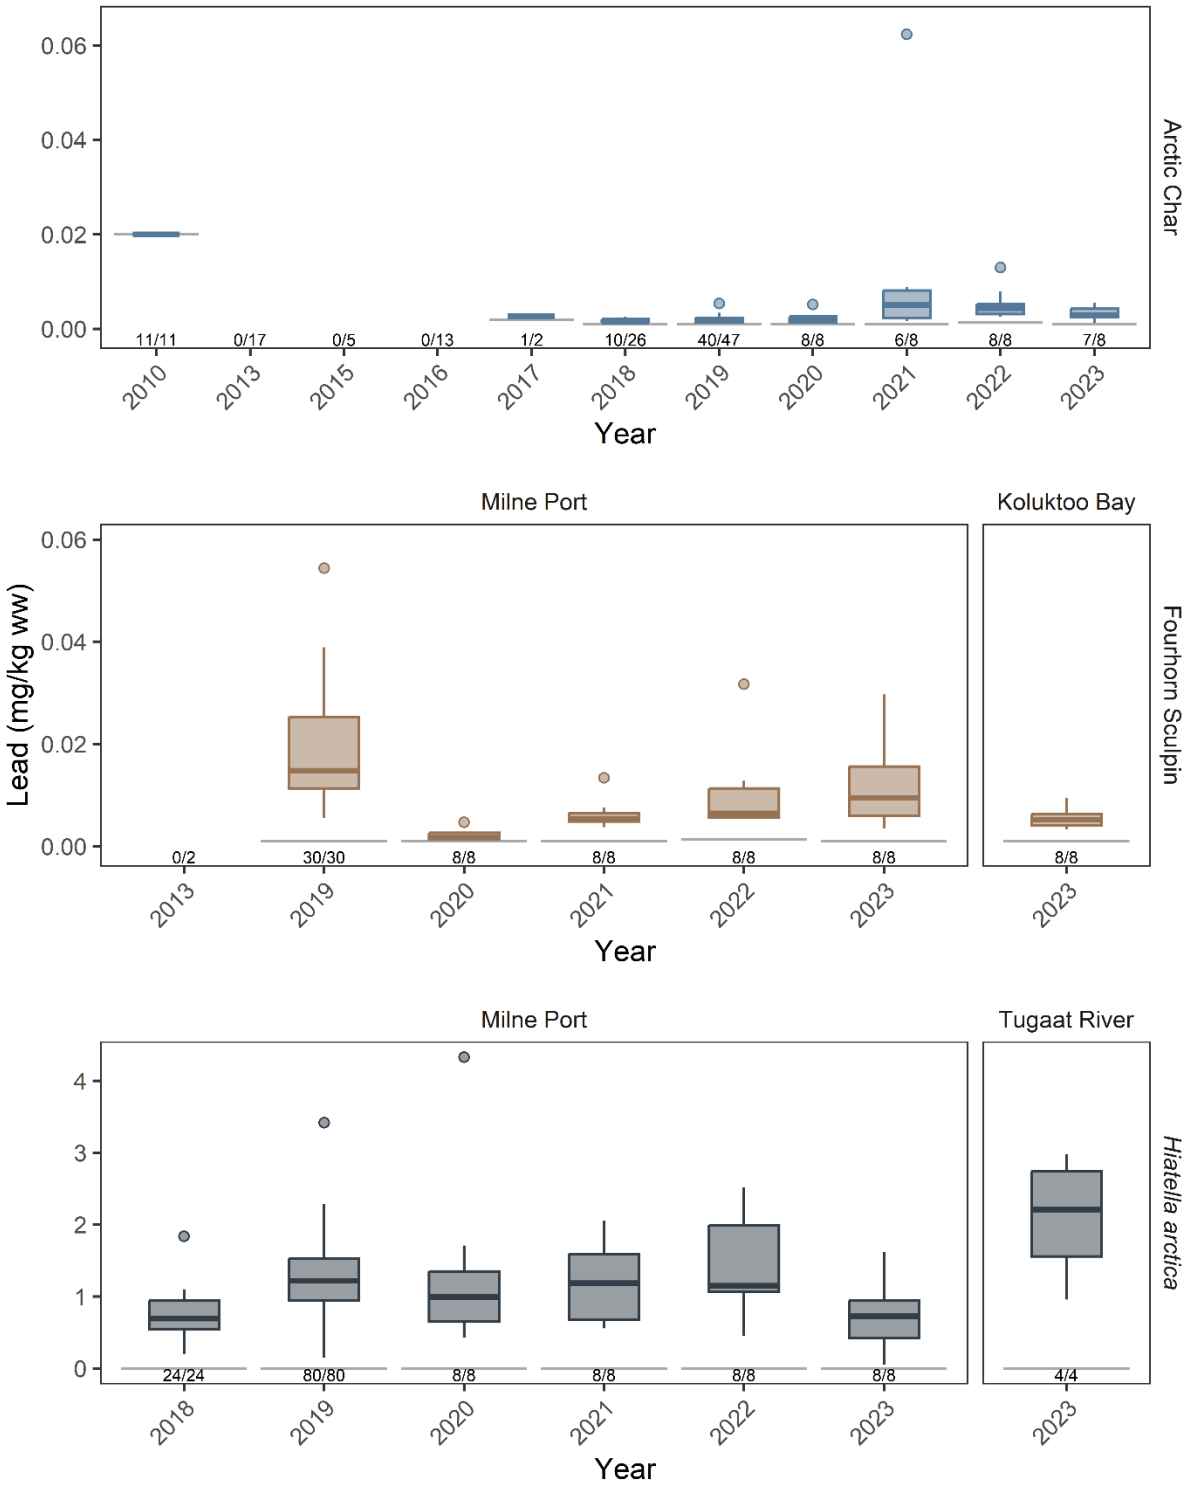
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits. One value for Arctic Char (3.27 mg/kg ww; 2010) not shown to allow for clearer visualization of the data.

Figure 7D-10: Concentrations of Chromium for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



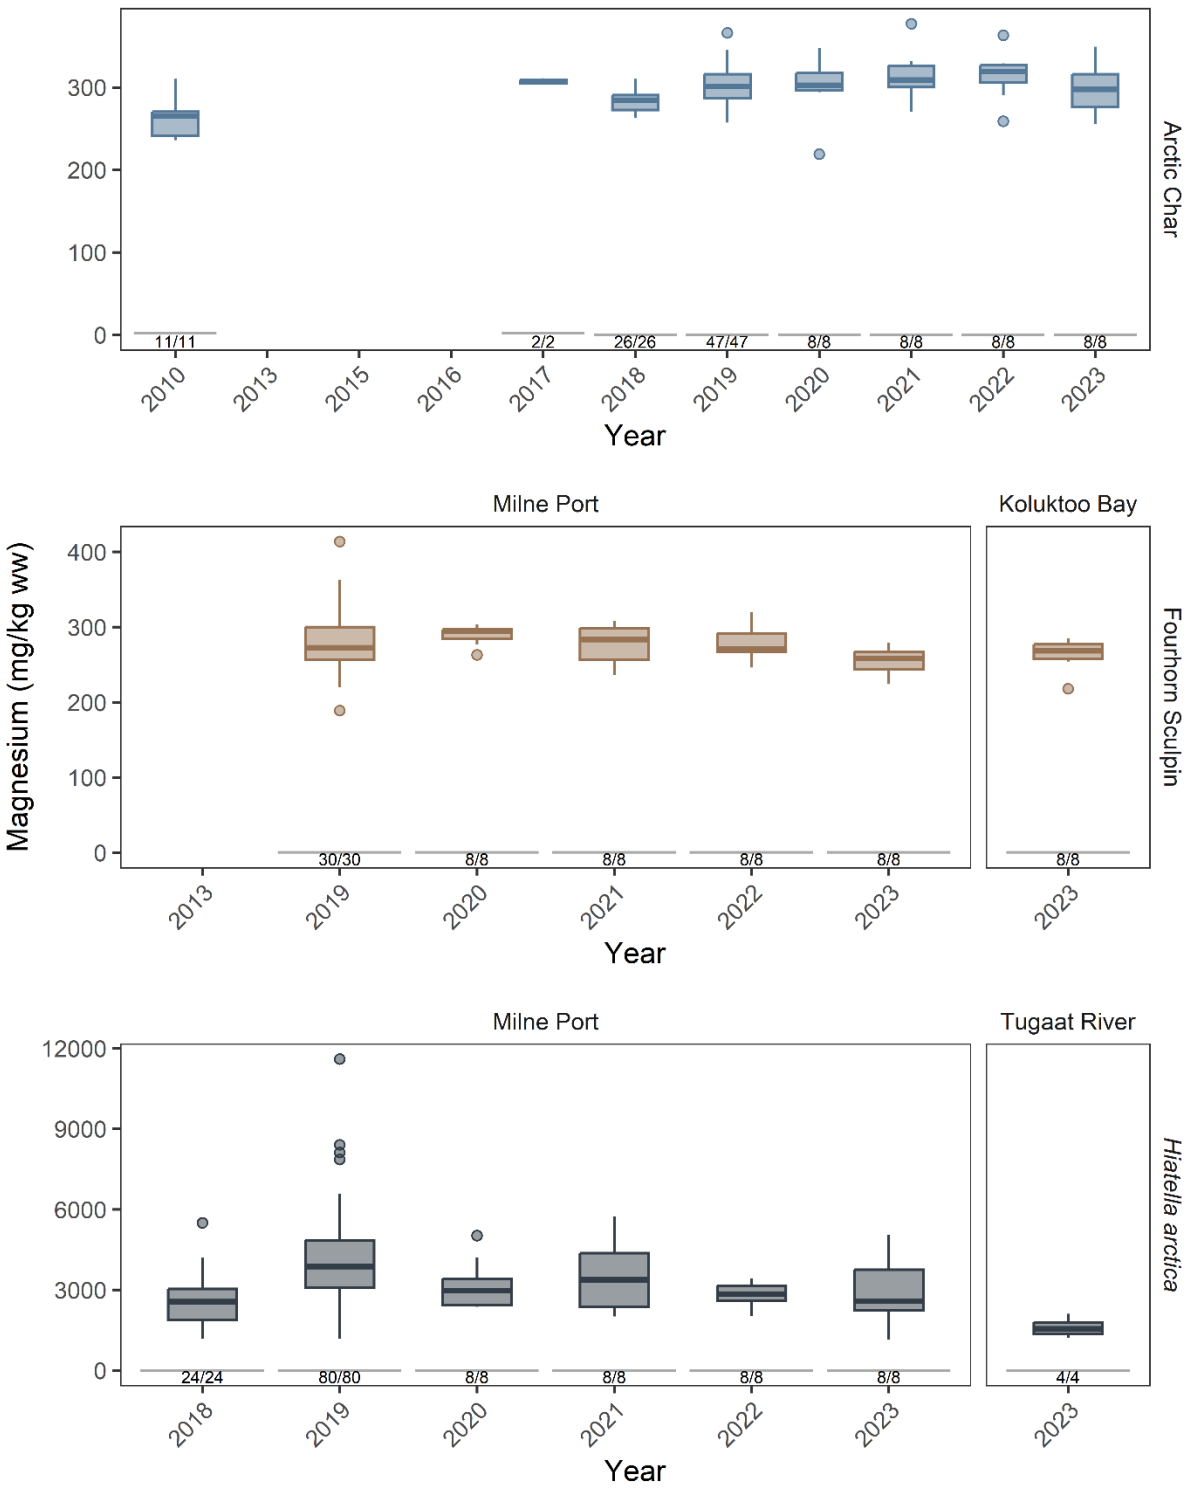
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits. Detection limit of 0.2 mg/kg for Arctic Char (2013, 2015, 2016) and Fourhorn Sculpin (2013), and one point for Fourhorn Sculpin (0.211 mg/kg ww; 2022) not shown to allow for clearer visualization of the data.

Figure 7D-11: Concentrations of Cobalt for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



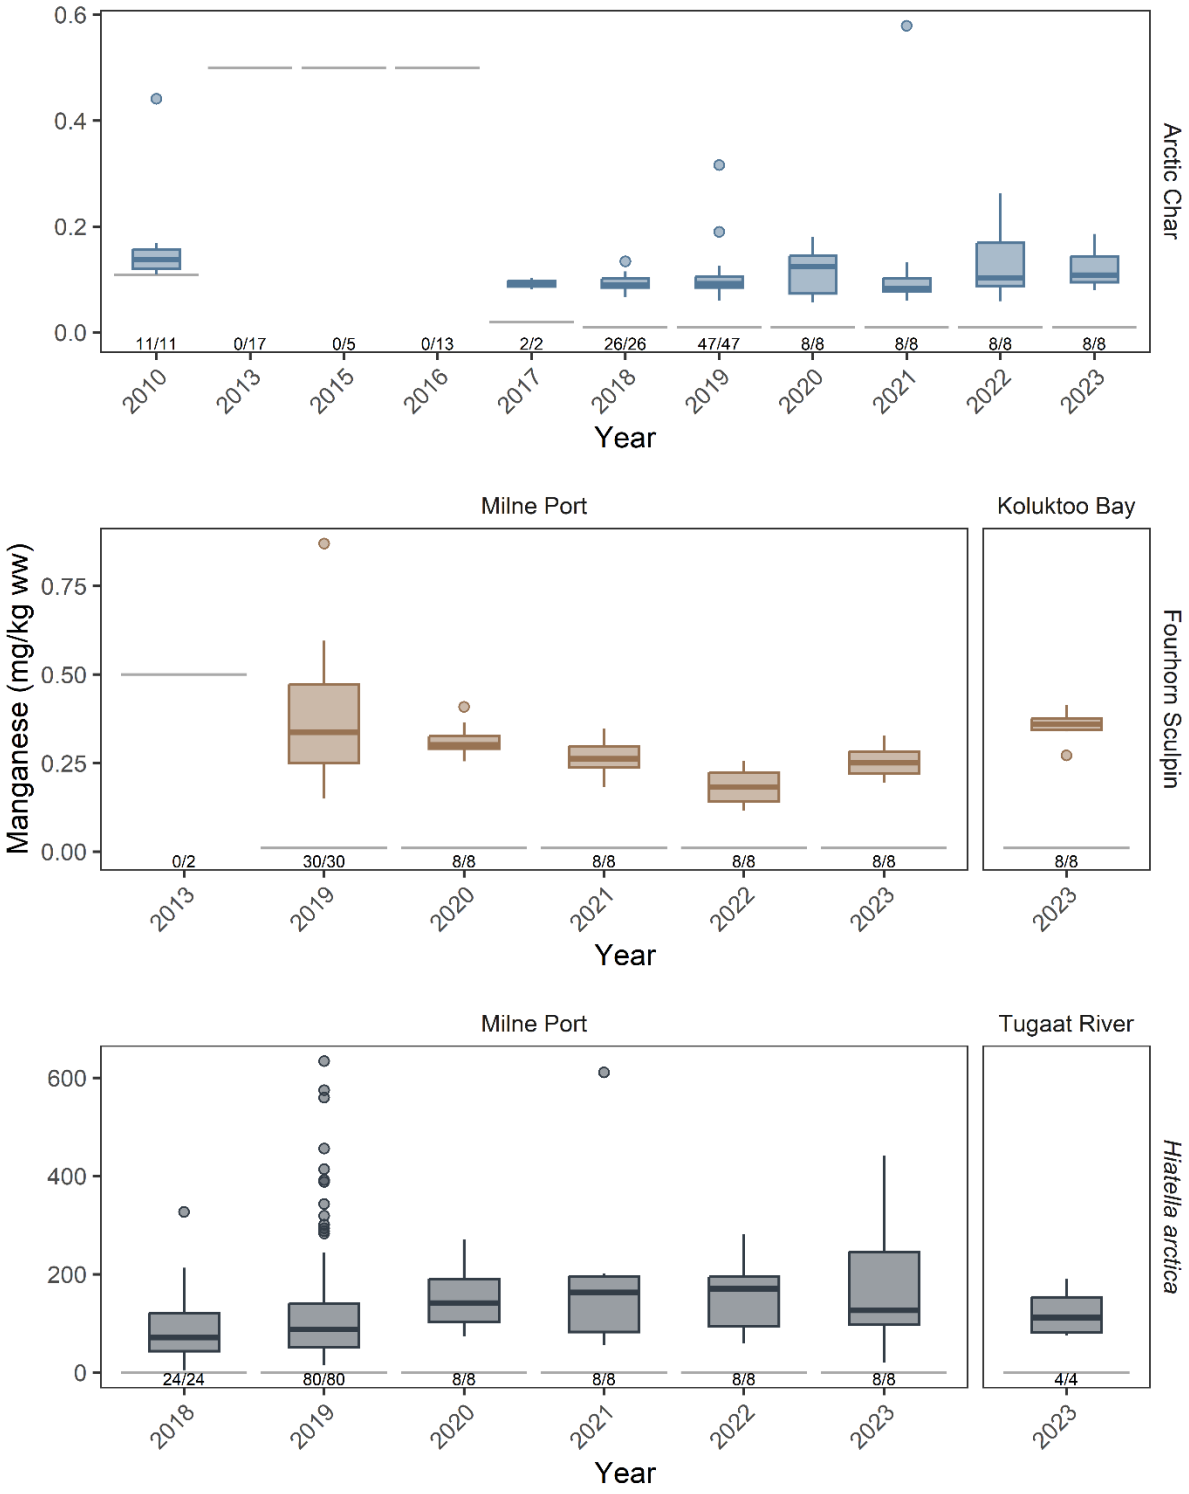
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-12: Concentrations of Copper for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



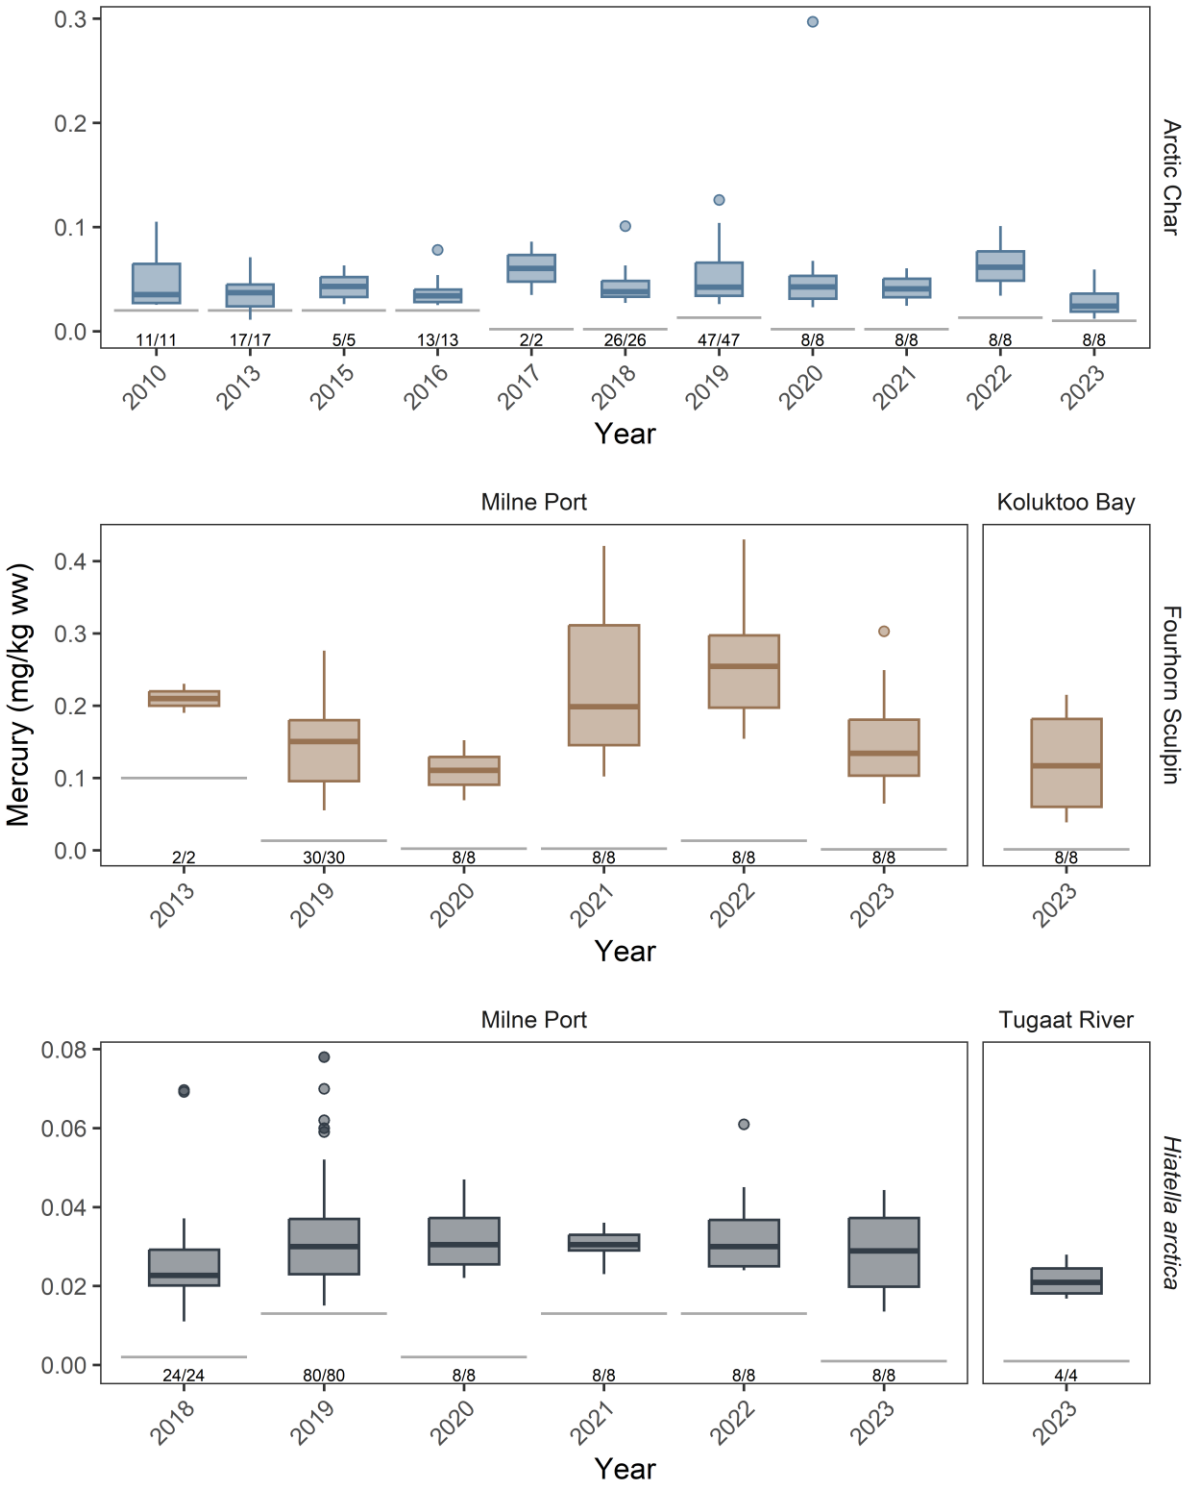
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as "n>DL/n". Values below DL are not shown in the plots. Grey lines indicate detection limits. One Arctic Char sample removed from 2022 (BAFF21UMLNGN06ARCH09, 87.15 mg/kg ww) to improve plotting.

Figure 7D-13: Concentrations of Iron for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



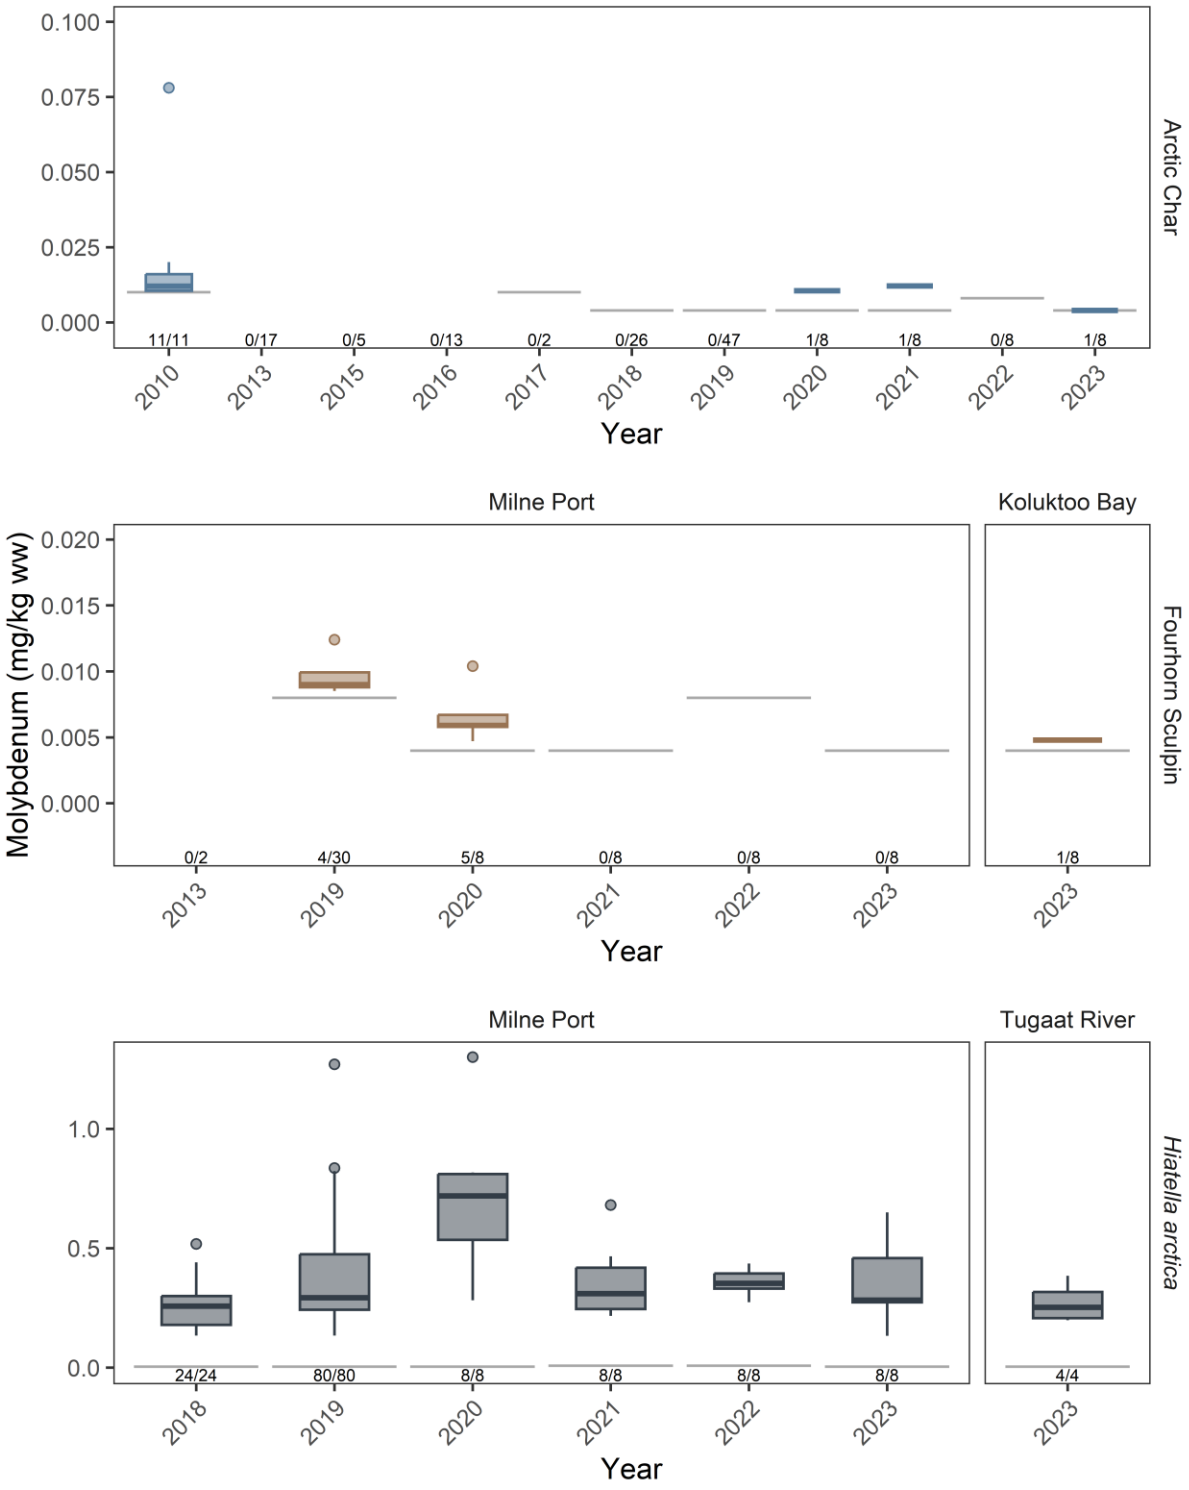
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits. Detection limit of 0.2 mg/kg ww for Arctic Char (2013, 2015, 2016) and Fourhorn Sculpin (2013) not shown to allow for clearer visualization of the data.

Figure 7D-14: Concentrations of Lead for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



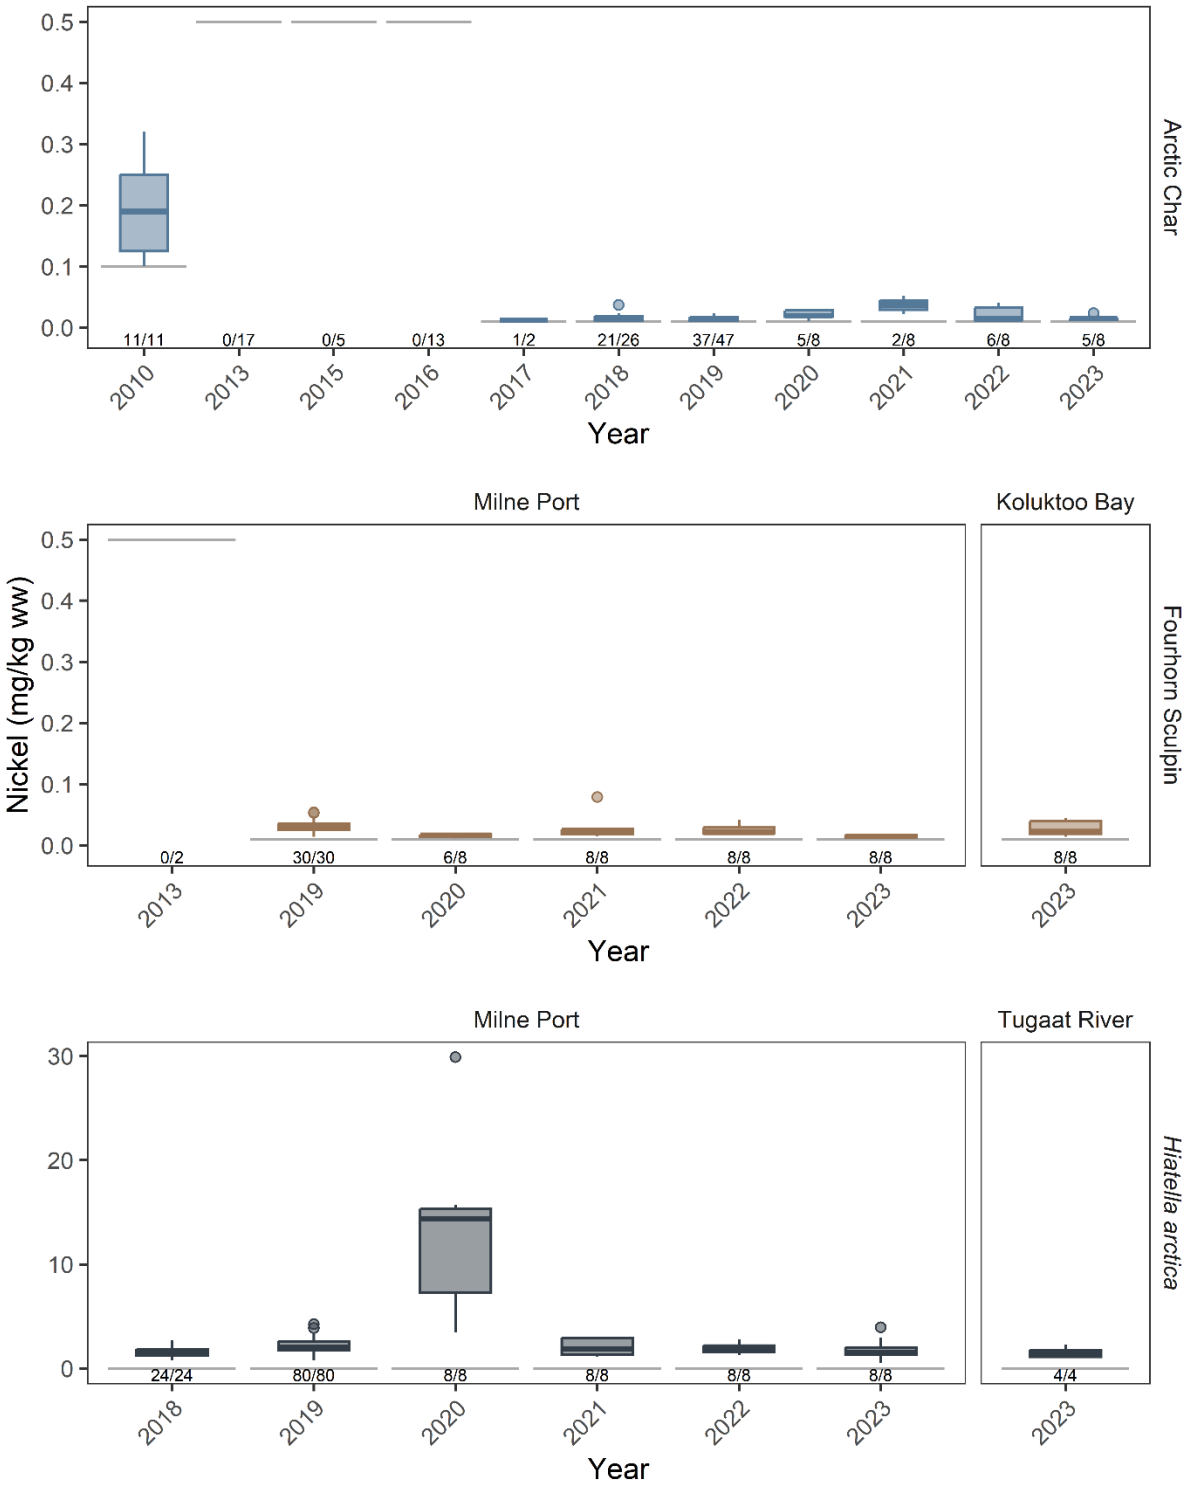
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-15: Concentrations of Magnesium for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



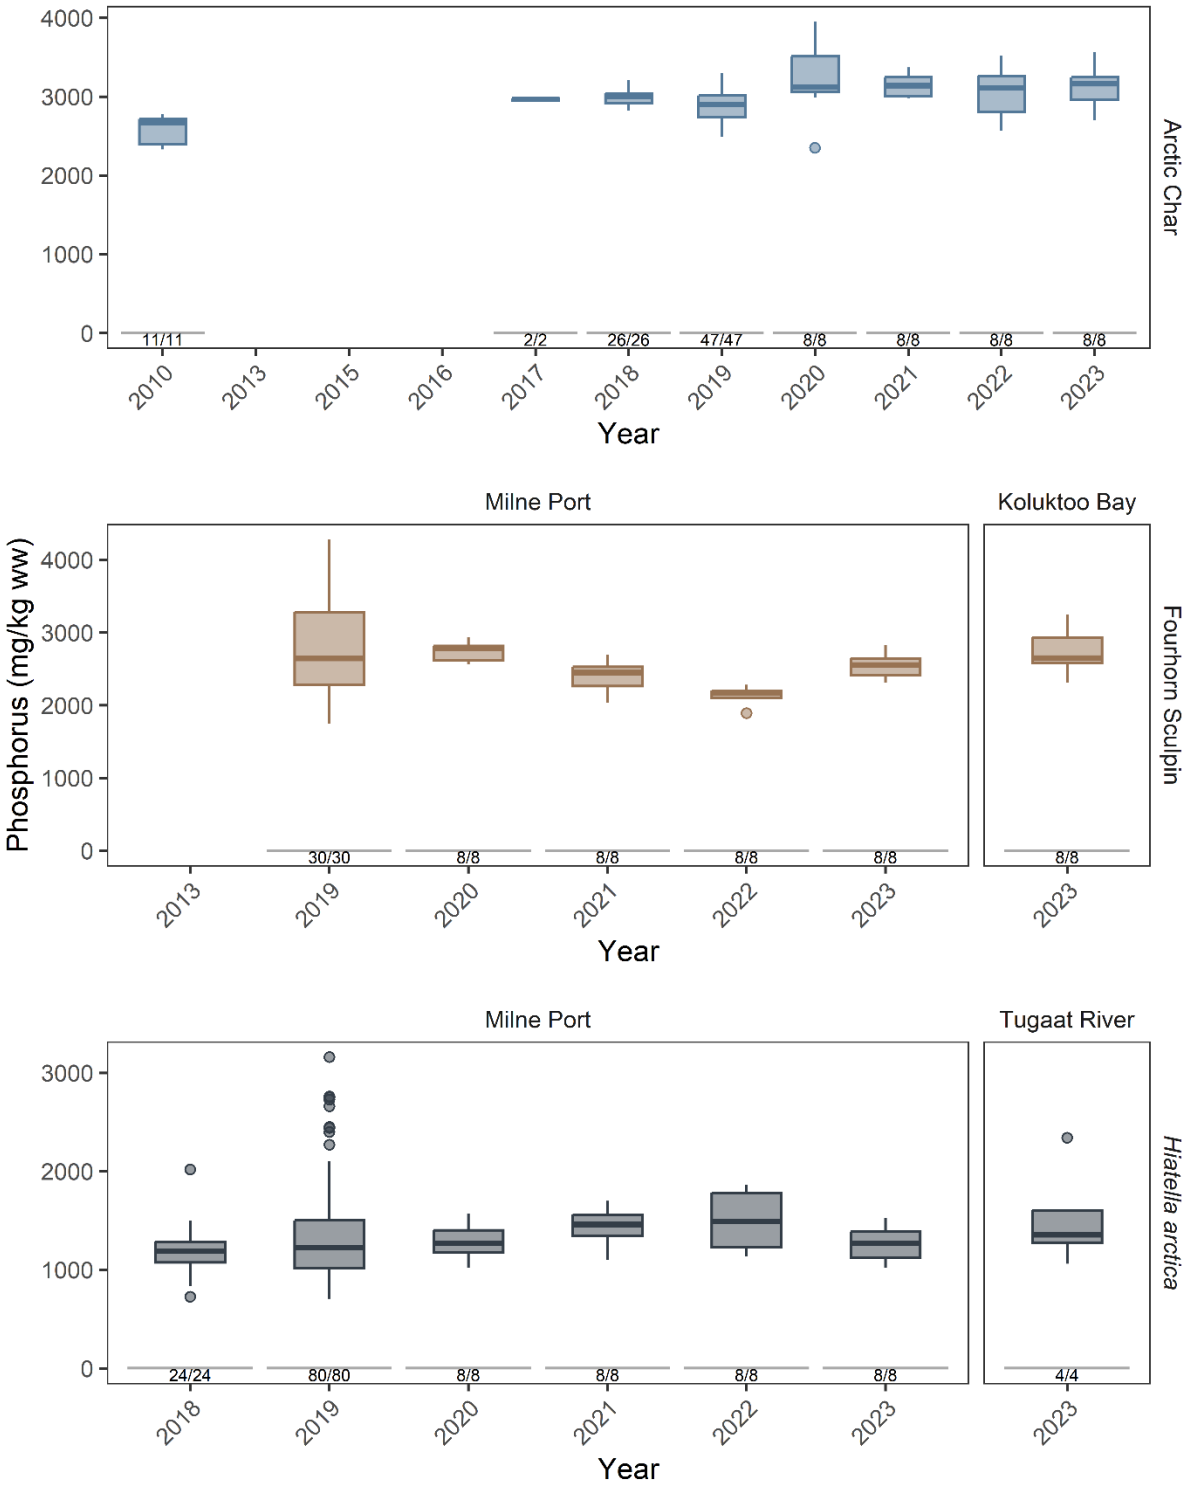
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-16: Concentrations of Manganese for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



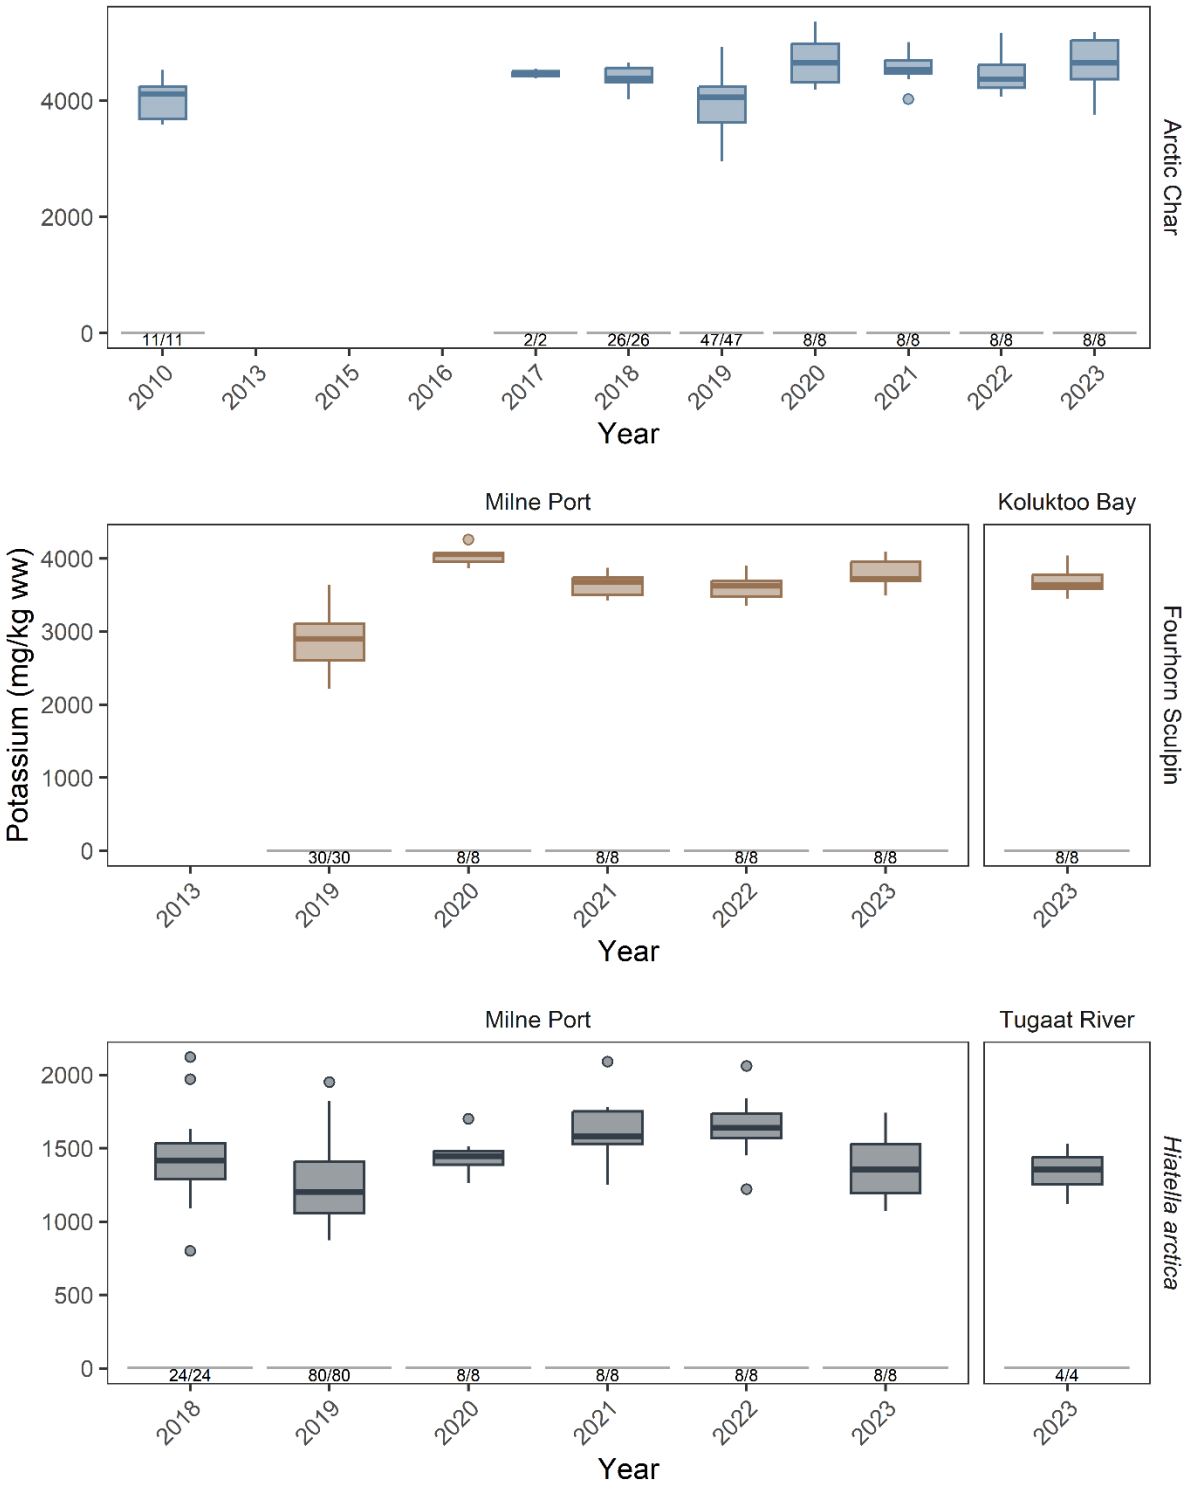
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-17: Concentrations of Mercury for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



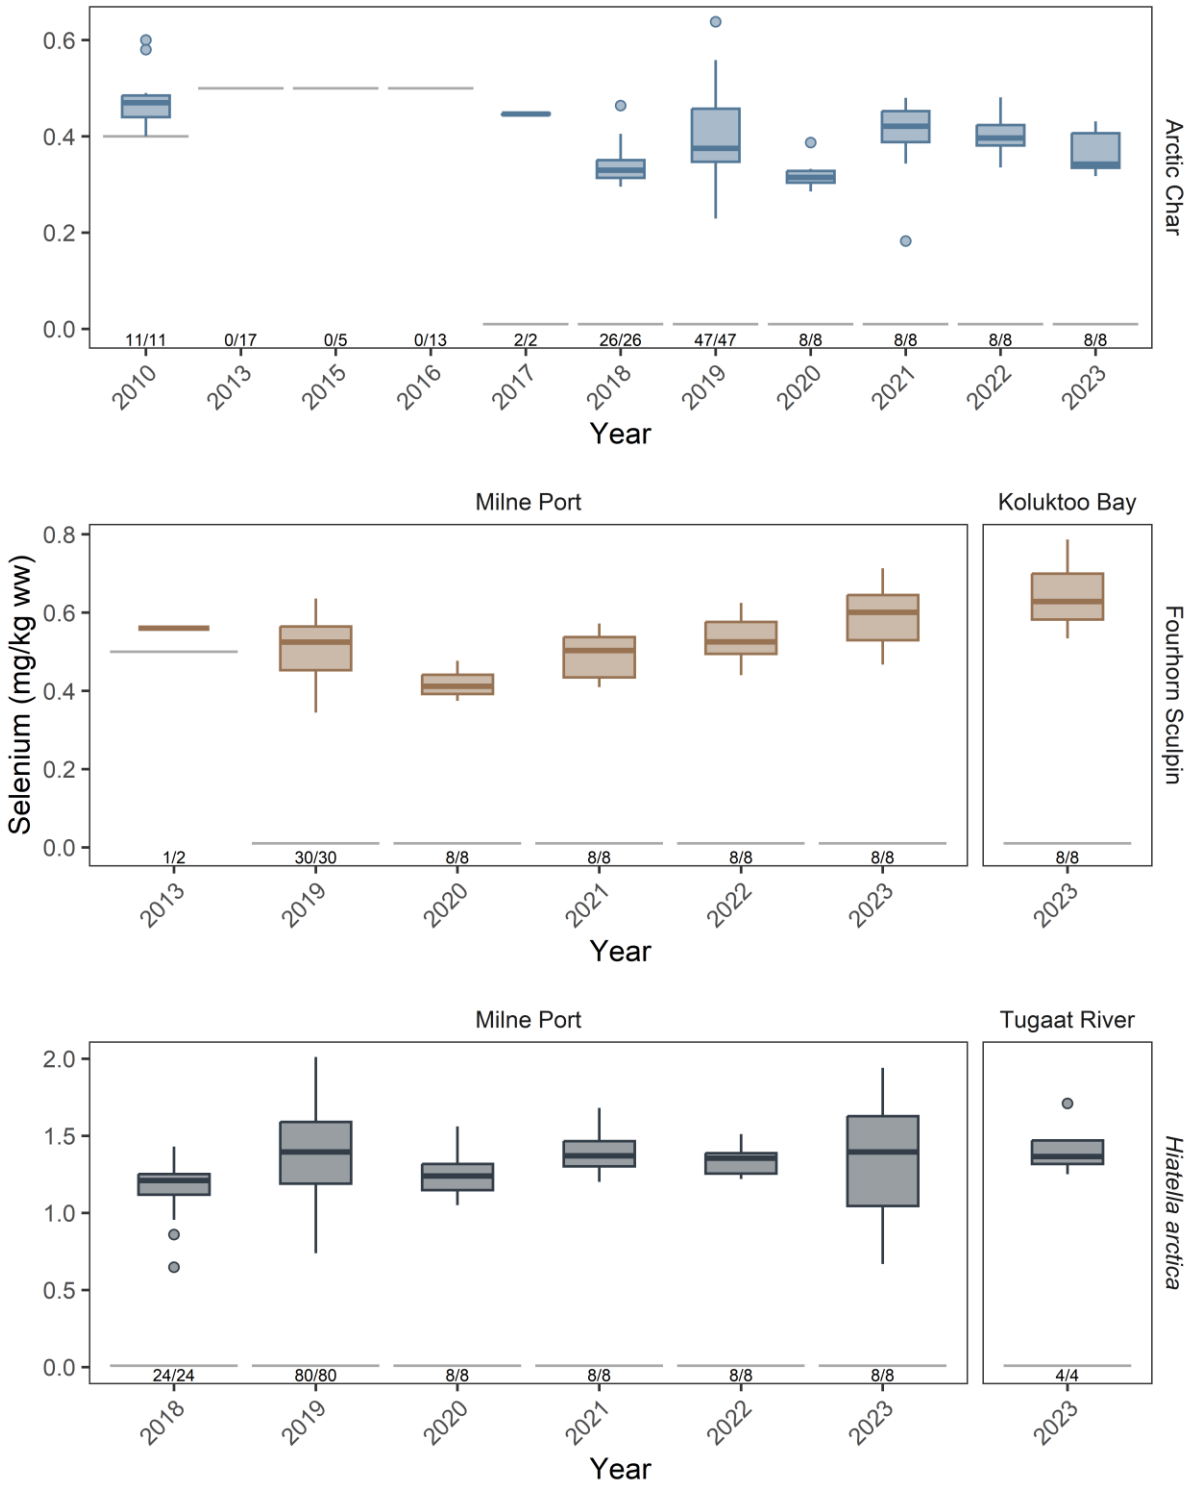
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits. Detection limit of 0.5 mg/kg ww for Arctic Char (2013, 2015, 2016) and Fourhorn Sculpin (2013) not shown to allow for clearer visualization of the data.

Figure 7D-18: Concentrations of Molybdenum for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



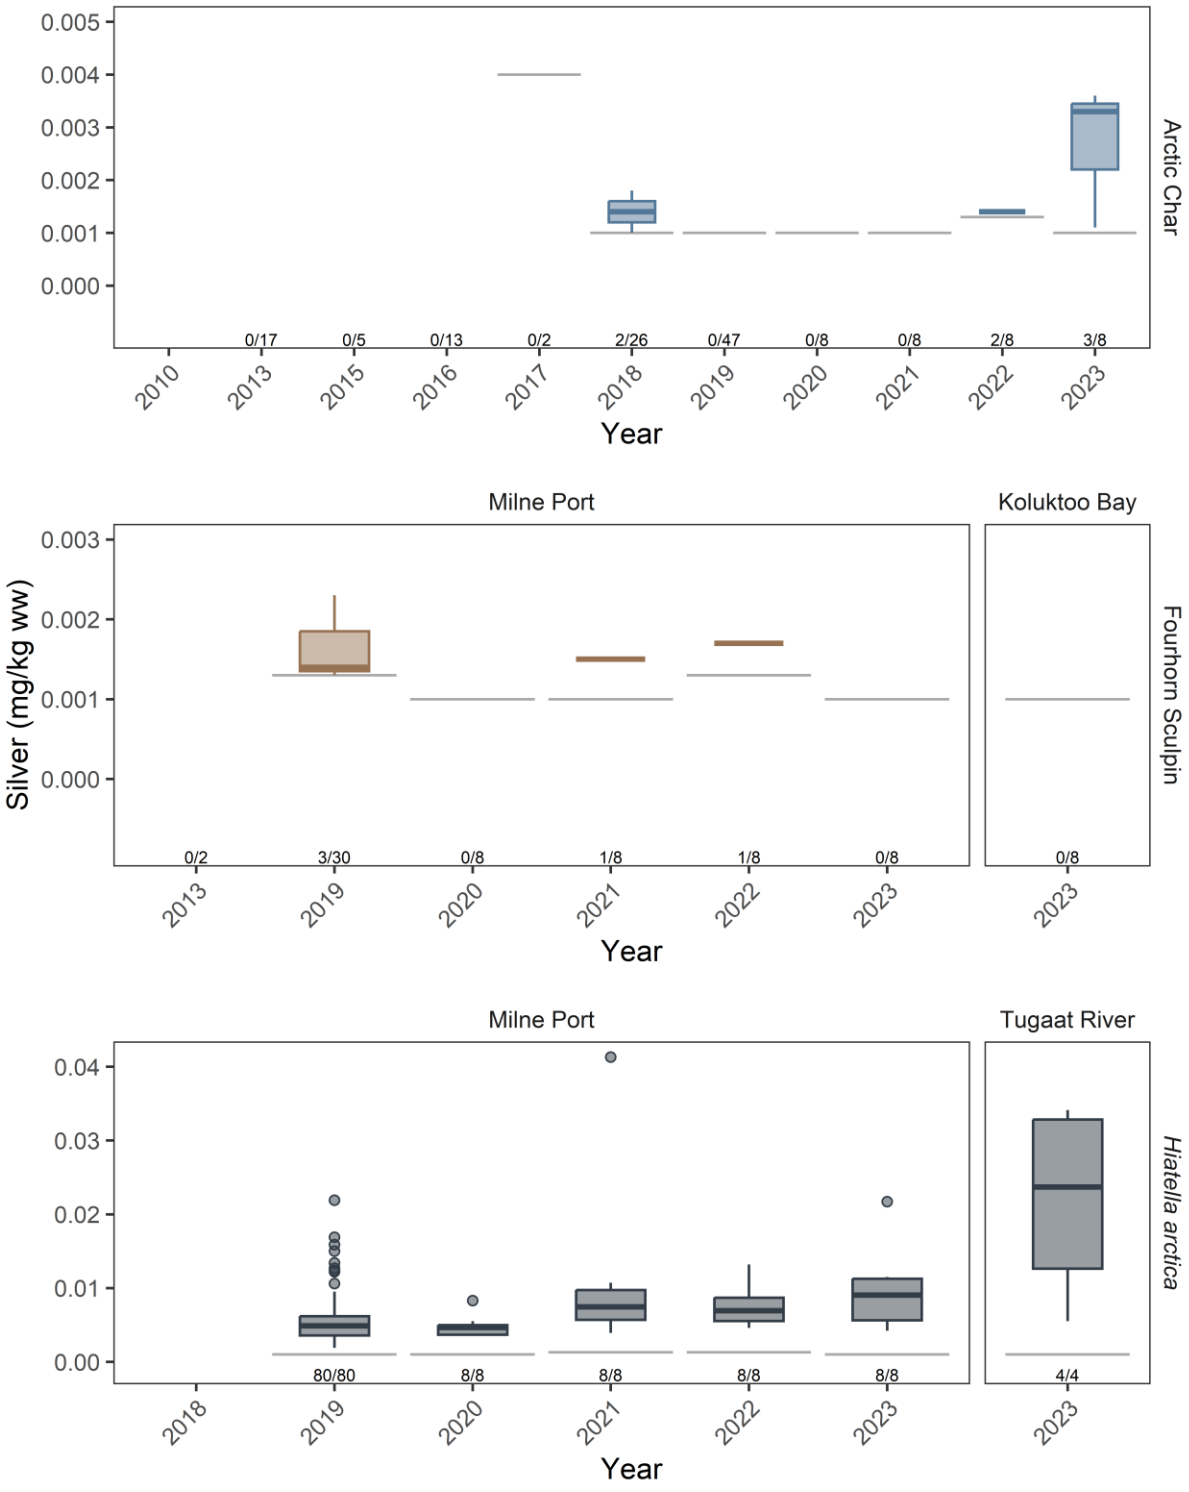
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits. One point for Arctic Char (1.62 mg/kg ww; 2010) not shown to allow for clearer visualization of the data.

Figure 7D-19: Concentrations of Nickel for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



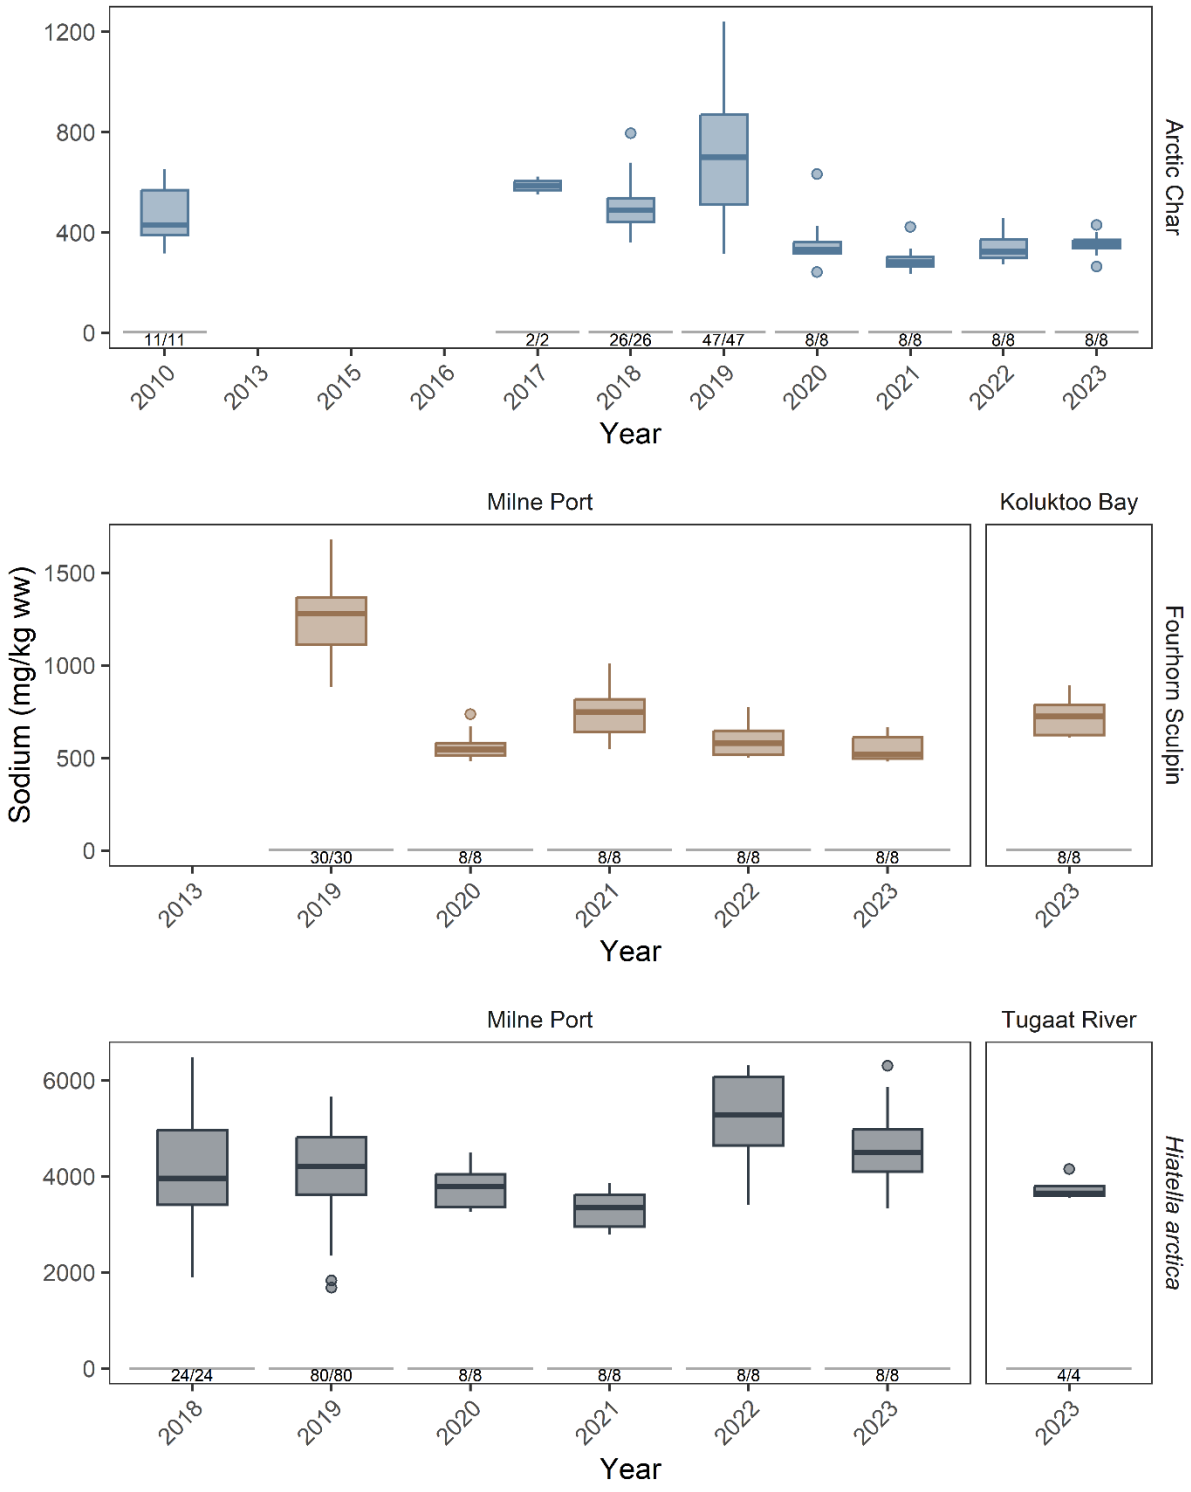
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-20: Concentrations of Phosphorus for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



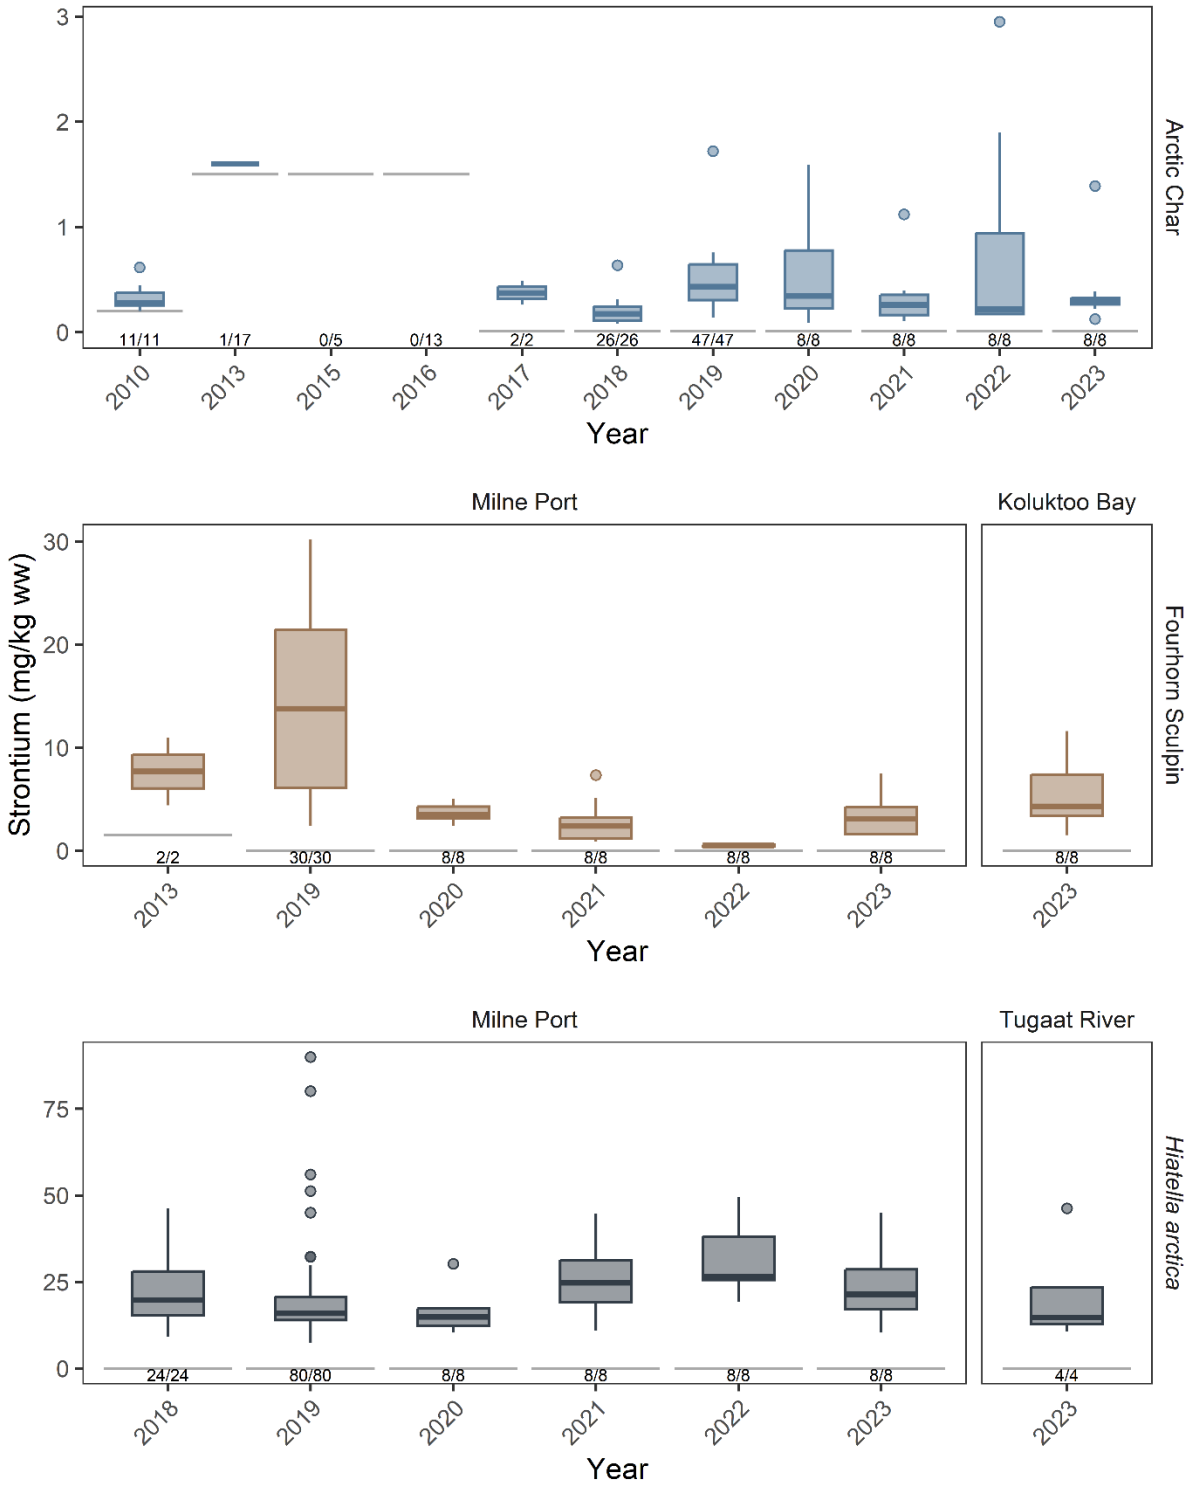
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-21: Concentrations of Potassium for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



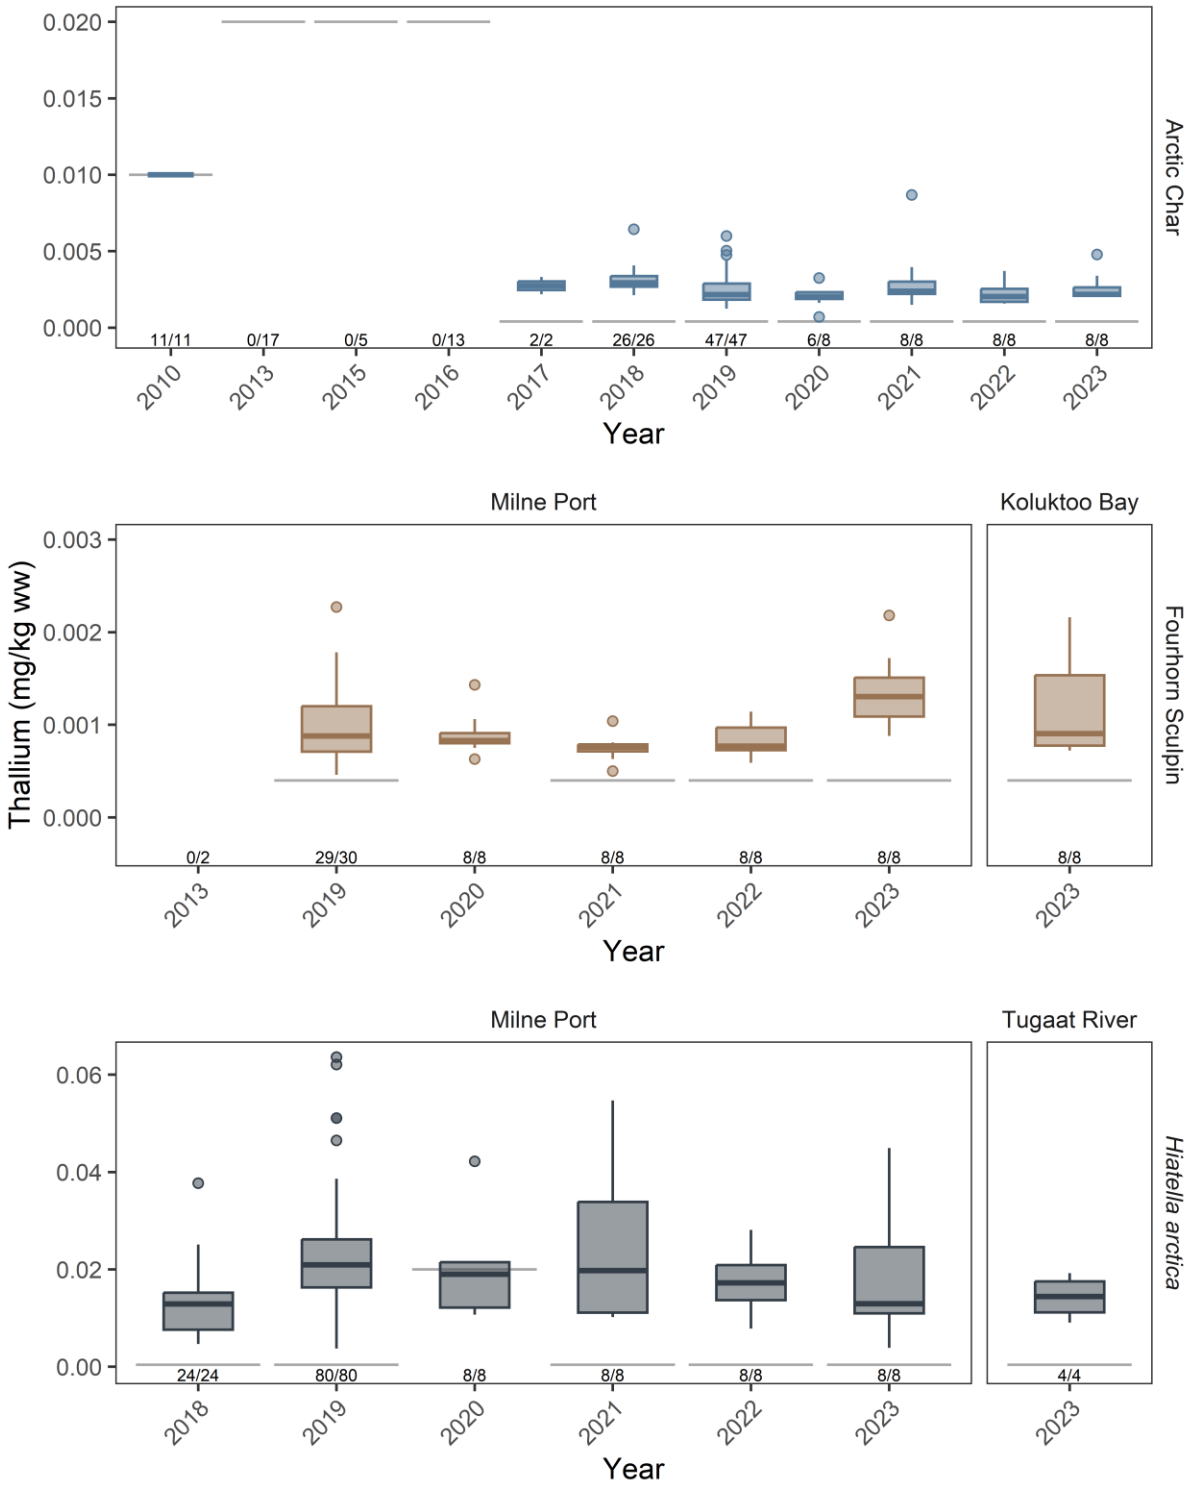
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-22: Concentrations of Selenium for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



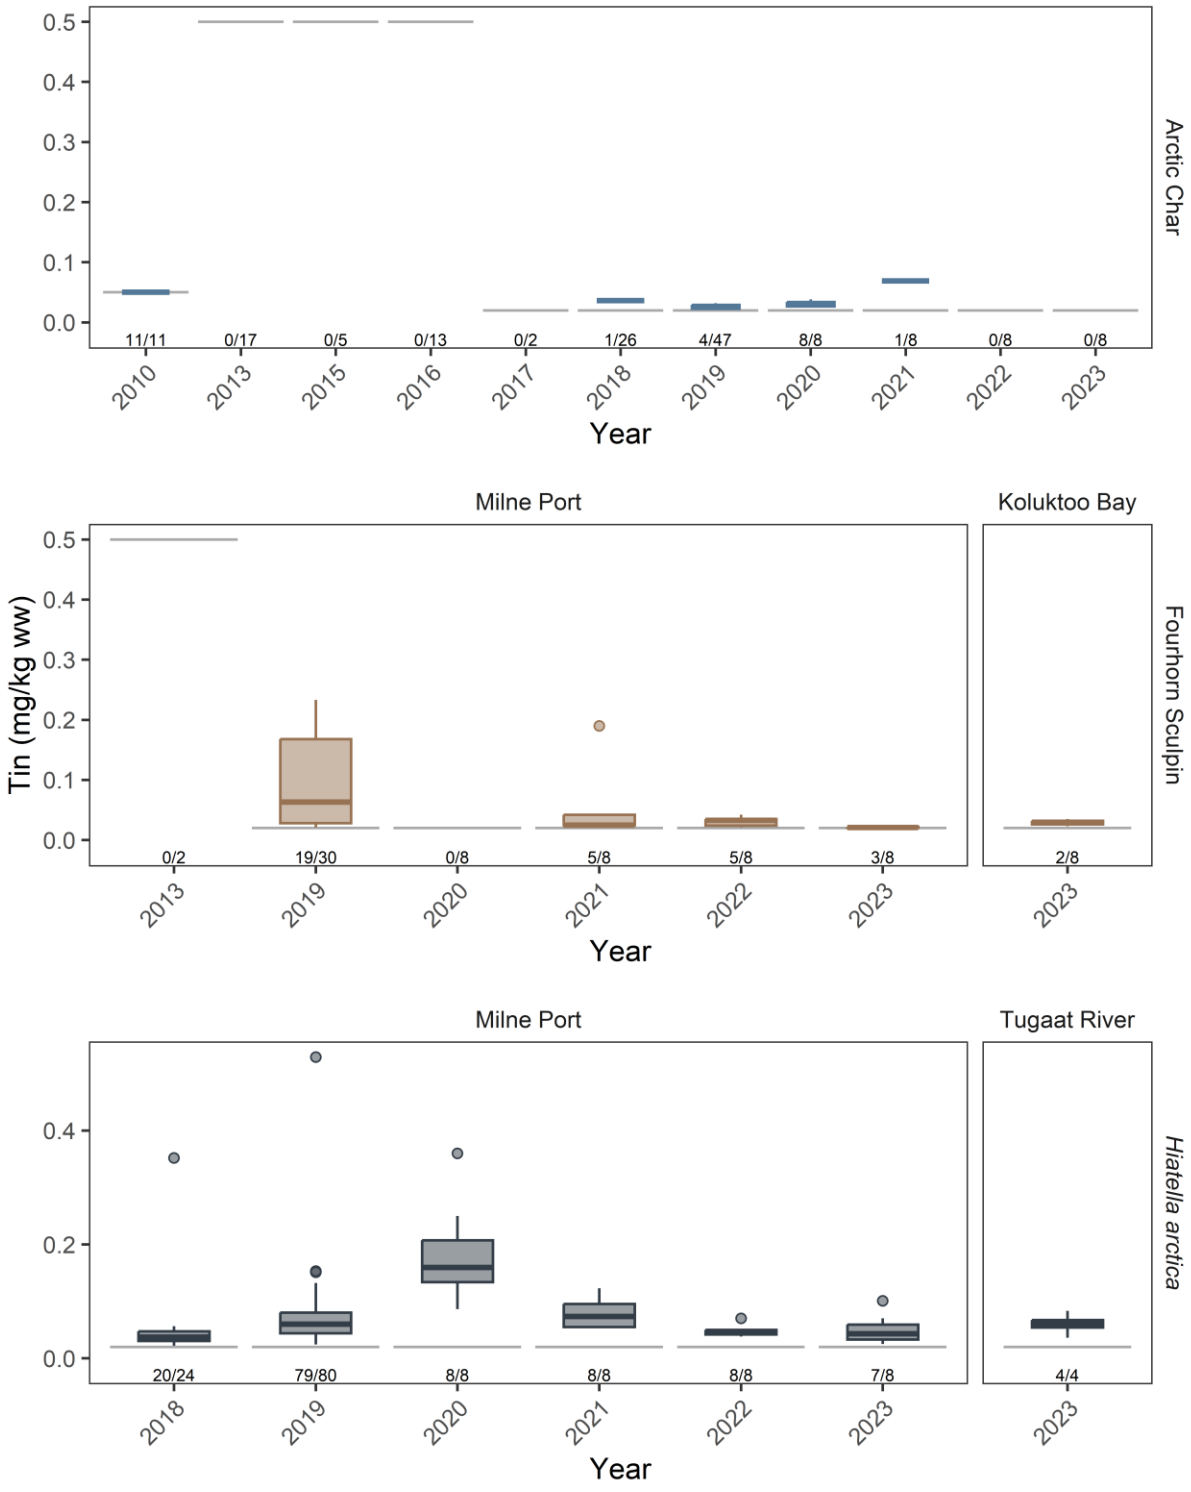
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits. Detection limit of 0.12 mg/kg ww for Arctic Char (2013, 2015, 2016) and Fourhorn Sculpin (2013) not shown to allow for clearer visualization of the data.

Figure 7D-23: Concentrations of Silver for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



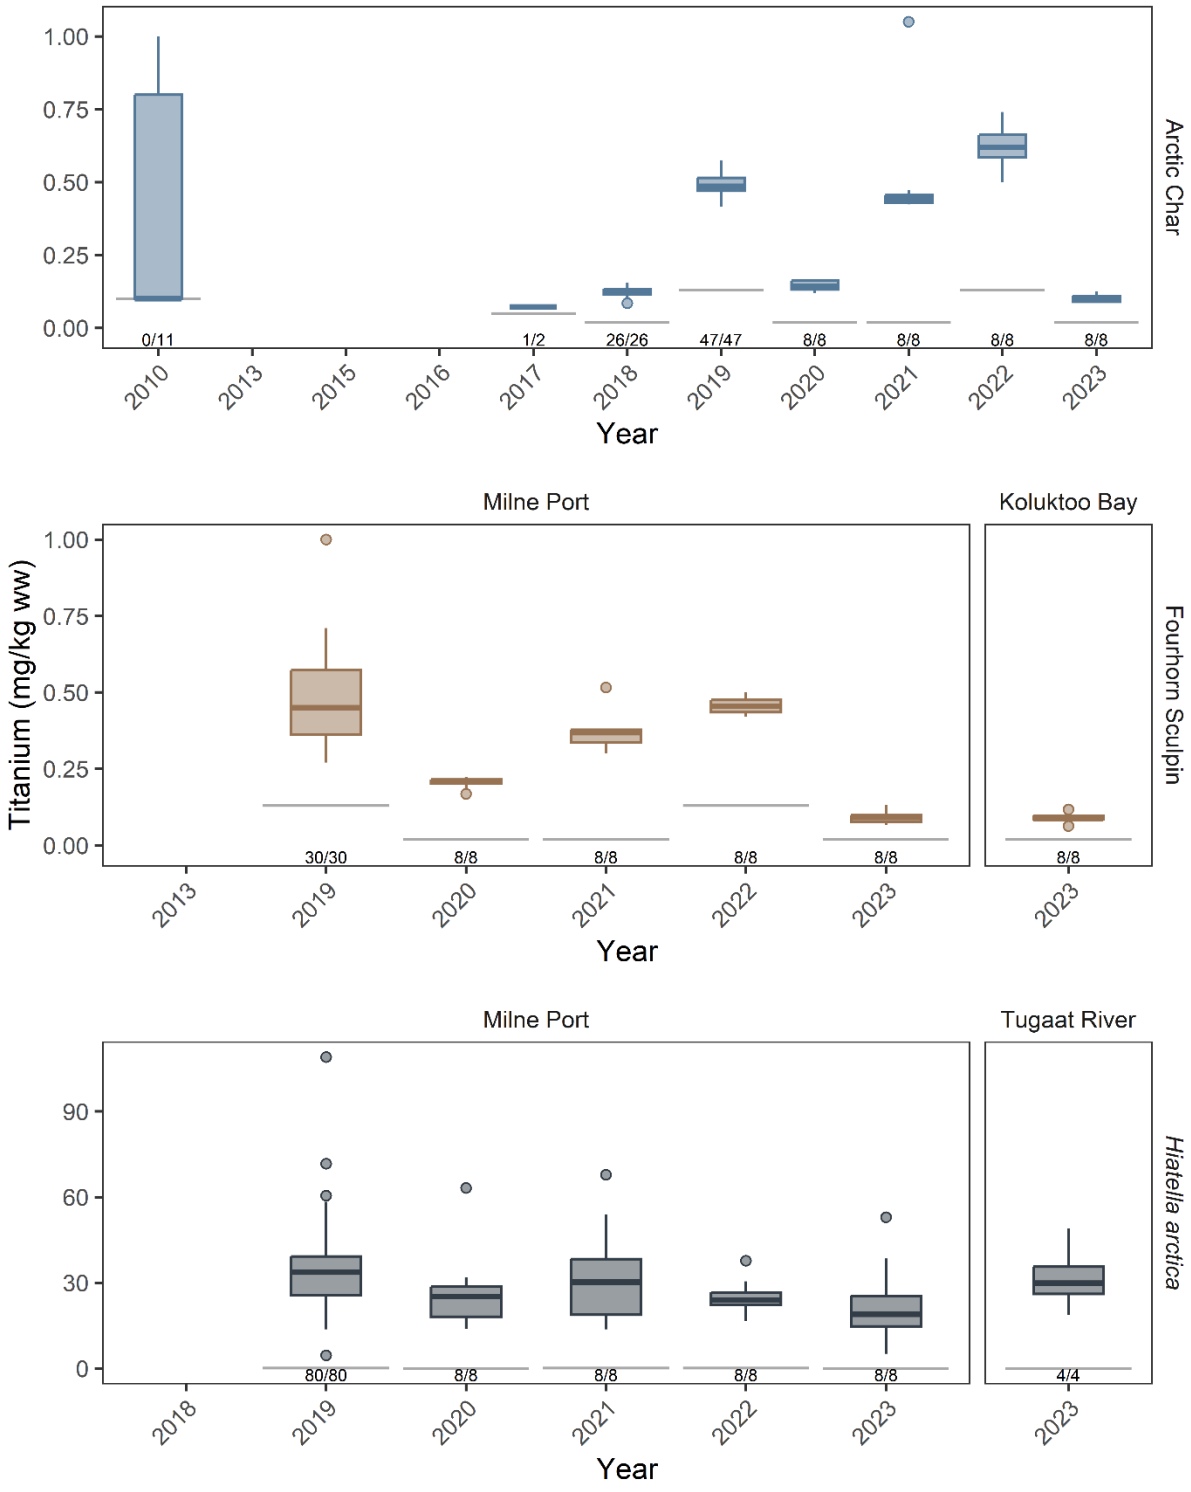
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-24: Concentrations of Sodium for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



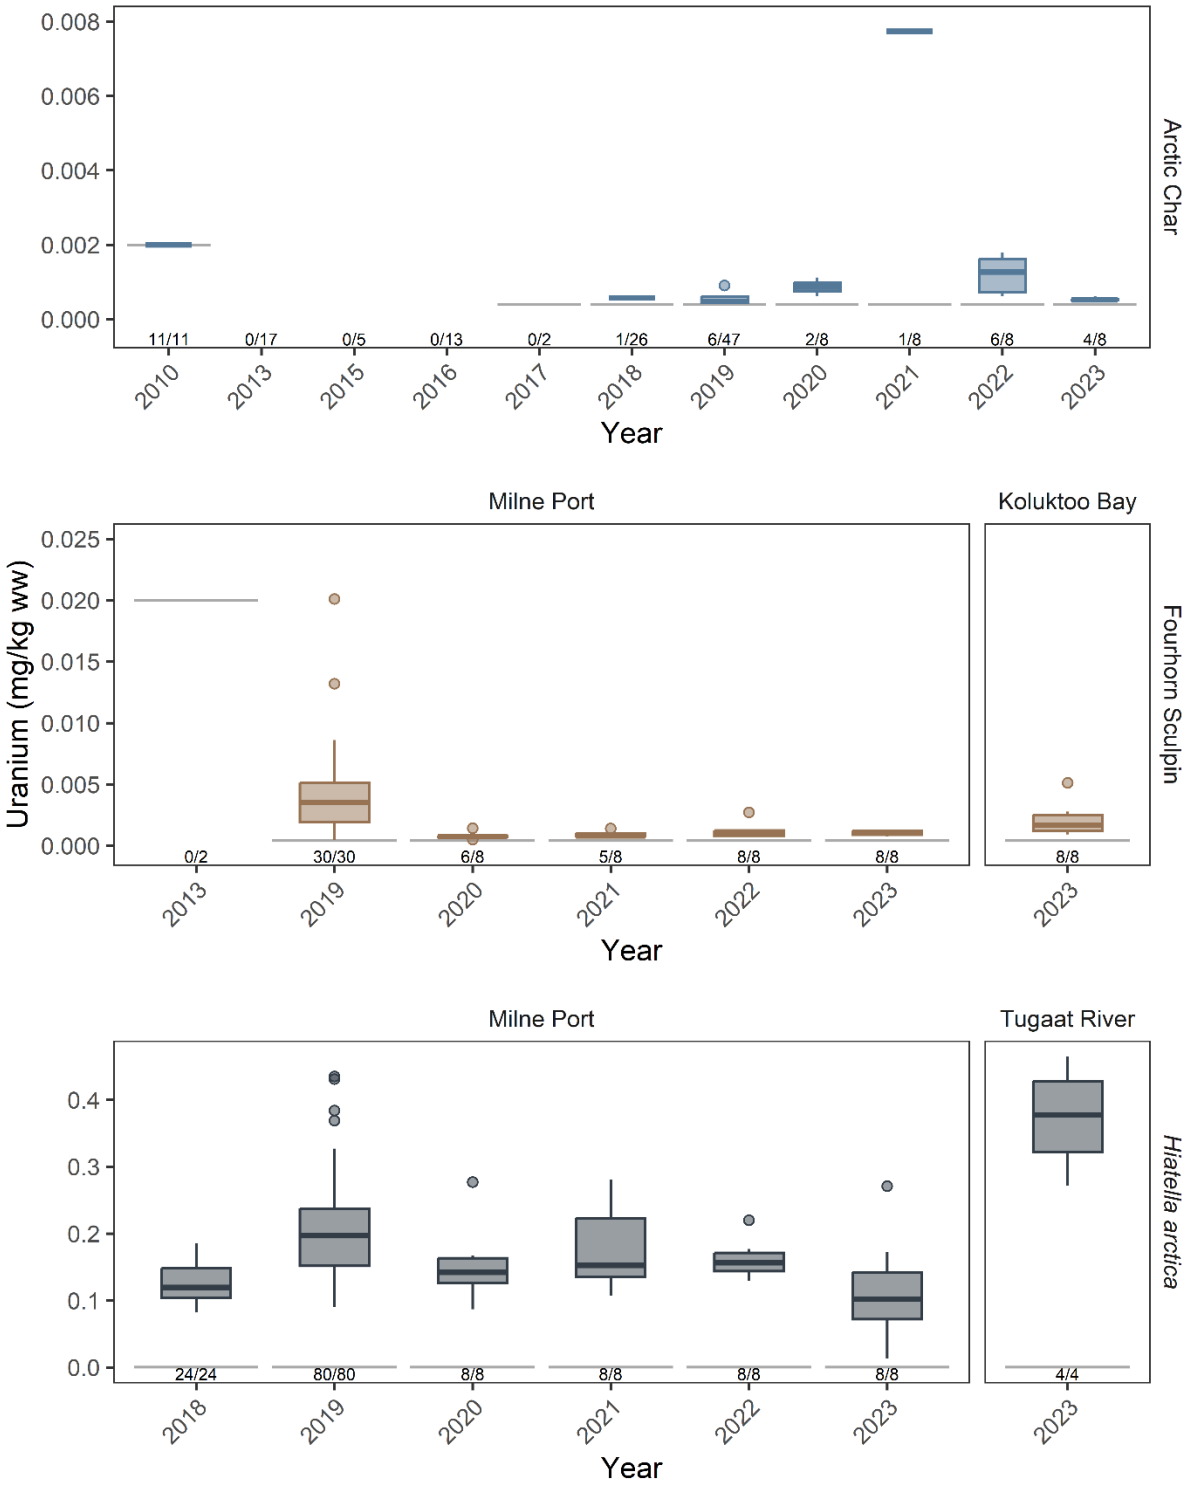
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-25: Concentrations of Strontium for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



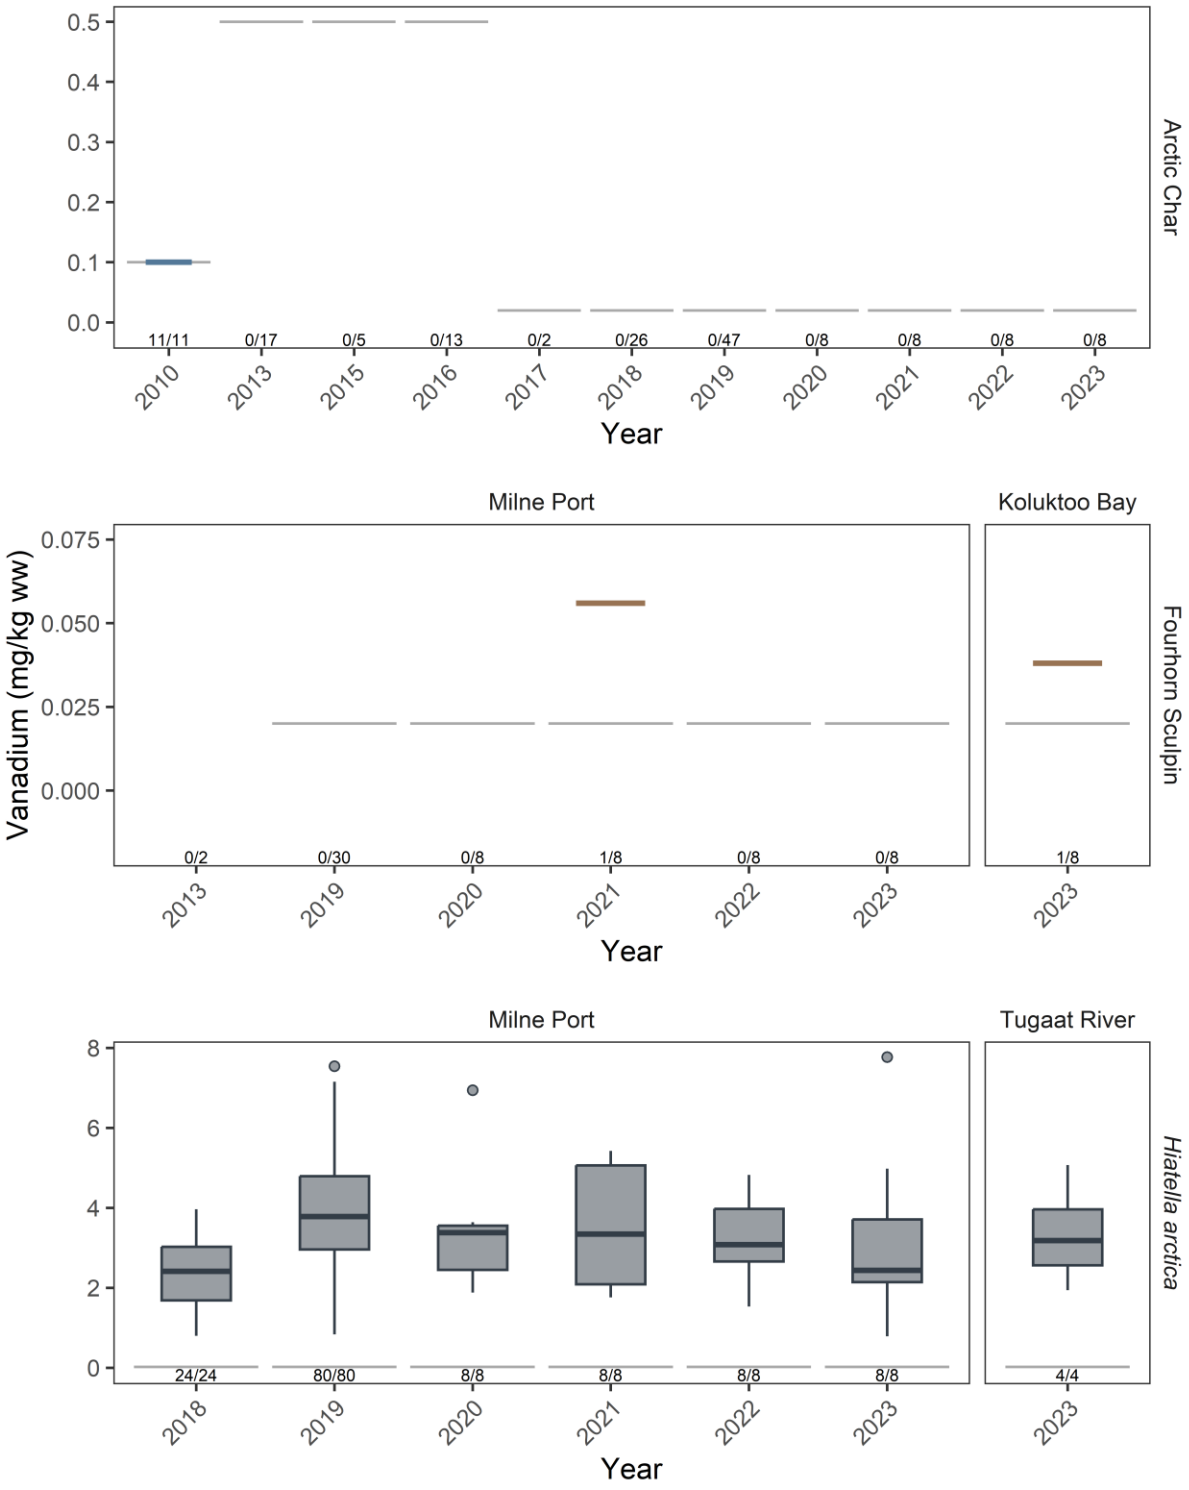
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits. Detection limit of 0.02 mg/kg ww for Fourhorn Sculpin (2013, 2020) not shown to allow for clearer visualization of the data.

Figure 7D-26: Concentrations of Thallium for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



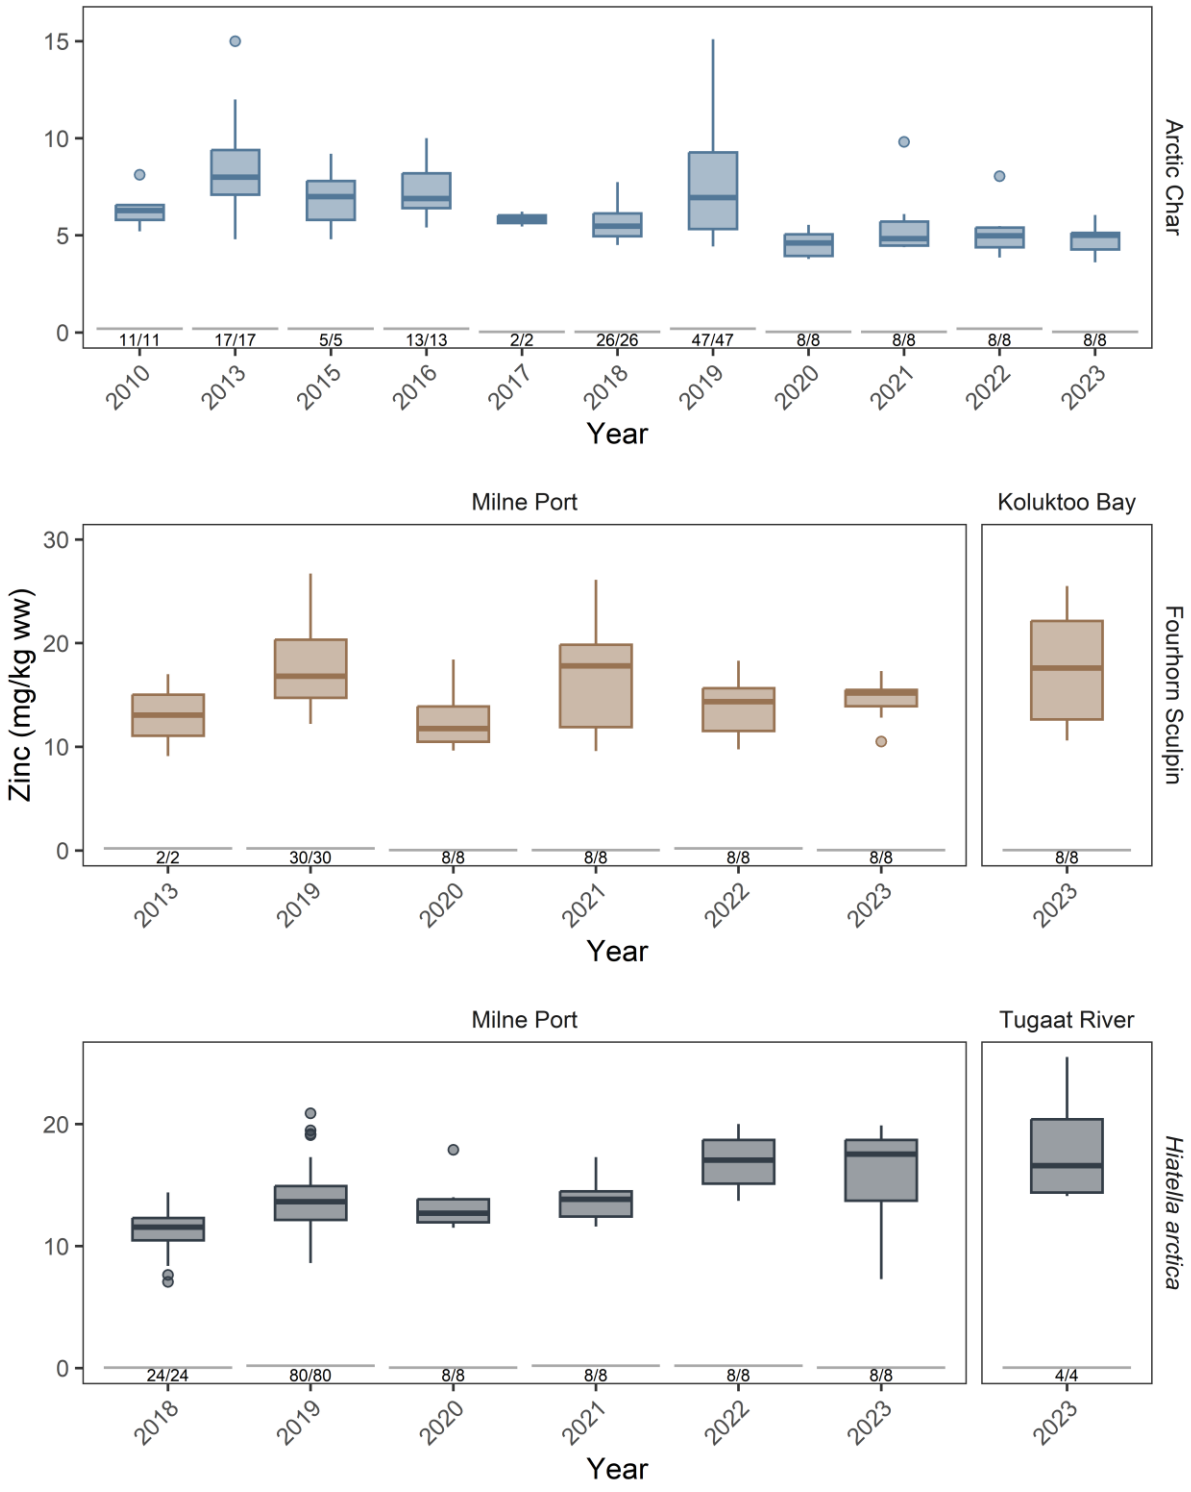
Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as "n>DL/n". Values below DL are not shown in the plots. Grey lines indicate detection limits. One point for Fourhorn Sculpin (1.41 mg/kg ww; 2019) not shown to allow for clearer visualization of the data.

Figure 7D-27: Concentrations of Tin for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits.

Figure 7D-28: Concentrations of Titanium for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023



Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits. Detection limit of 0.02 mg/kg ww for Arctic Char (2013, 2015, 2016) and Fourhorn Sculpin (2013) not shown to allow for clear visualization of the data.

Figure 7D-29: Concentrations of Uranium for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023

Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits. Detection limit of 0.5 mg/kg ww for Fourhorn Sculpin (2013) not shown to allow for clearer visualization of the data.

Figure 7D-30: Concentrations of Vanadium for *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023

Total sample size (n) and number of samples above detection limits (n>DL) are shown above the x-axis as “n>DL/n”. Values below DL are not shown in the plots. Grey lines indicate detection limits. One point for Arctic Char (73.2 mg/kg ww; 2010) not shown to allow for clearer visualization of the data.

Figure 7D-31: Concentrations of Zinc for Arctic Char, Fourhorn Sculpin and *Hiatella arctica* Tissue Sampled from the Milne Port Area and Reference Areas, 2010 to 2023

Remarks:

Bureau Veritas is accredited to ISO/IEC 17025 for specific parameters on scopes of accreditation. Unless otherwise noted, procedures used by Bureau Veritas are based upon recognized Provincial, Federal or US method compendia such as CCME, MELCC, EPA, APHA.

All work recorded herein has been done in accordance with procedures and practices ordinarily exercised by professionals in Bureau Veritas' profession using accepted testing methodologies, quality assurance and quality control procedures (except where otherwise agreed by the client and Bureau Veritas in writing). All data is in statistical control and has met quality control and method performance criteria unless otherwise noted. All method blanks are reported; unless indicated otherwise, associated sample data are not blank corrected. Where applicable, unless otherwise noted, Measurement Uncertainty has not been accounted for when stating conformity to the referenced standard.

Bureau Veritas liability is limited to the actual cost of the requested analyses, unless otherwise agreed in writing. There is no other warranty expressed or implied. Bureau Veritas has been retained to provide analysis of samples provided by the Client using the testing methodology referenced in this report. Interpretation and use of test results are the sole responsibility of the Client and are not within the scope of services provided by Bureau Veritas, unless otherwise agreed in writing. Bureau Veritas is not responsible for the accuracy or any data impacts, that result from the information provided by the customer or their agent.

Solid sample results, except biota, are based on dry weight unless otherwise indicated. Organic analyses are not recovery corrected except for isotope dilution methods.
Results relate to samples tested. When sampling is not conducted by Bureau Veritas, results relate to the supplied samples tested.
This Certificate shall not be reproduced except in full, without the written approval of the laboratory.
Reference Method suffix “m” indicates test methods incorporate validated modifications from specific reference methods to improve performance.
* RPDs calculated using raw data. The rounding of final results may result in the apparent difference.

RDL = Reportable Detection Limit
(1) Matrix spike non calculable due to high concentration of original analyte.
Detection limits raised due to dilution to bring analyte within the calibrated range.
(2) Detection limits raised due to dilution to bring analyte within the calibrated range.

RDL = Reportable Detection Limit

(1) Matrix spike exceeds acceptance limits due to probable matrix interference.

(2) Duplicate exceeds acceptance criteria due to sample non homogeneity. Reanalysis yields similar results.

Duplicate: Paired analysis of a separate portion of the same sample. Used to evaluate the variance in the measurement.

Matrix Spike: A sample to which a known amount of the analyte of interest has been added. Used to evaluate sample matrix interference.

QC Standard: A sample of known concentration prepared by an external agency under stringent conditions. Used as an independent check of method accuracy.

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

NC (Duplicate RPD): The duplicate RPD was not calculated. The concentration in the sample and/or duplicate was too low to permit a reliable RPD calculation (absolute difference <= 2x RDL).

(1) Recovery or RPD for this parameter is outside control limits. The overall quality control for this analysis meets acceptability criteria.

VALIDATION SIGNATURE PAGE

The analytical data and all QC contained in this report were reviewed and validated by:

David Huang, M.Sc., P.Chem., QP, Scientific Services Manager

Bureau Veritas has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per ISO/IEC 17025, signing the reports. For Service Group specific validation, please refer to the Validation Signatures page if included, otherwise available by request. For Department specific Analyst/Supervisor validation names, please refer to the Test Summary section if included, otherwise available by request. This report is authorized by Raphael Kwan, Senior Manager, BC and Yukon Regions responsible for British Columbia Environmental laboratory operations.

Remarks:

Bureau Veritas is accredited to ISO/IEC 17025 for specific parameters on scopes of accreditation. Unless otherwise noted, procedures used by Bureau Veritas are based upon recognized Provincial, Federal or US method compendia such as CCME, MELCC, EPA, APHA.

All work recorded herein has been done in accordance with procedures and practices ordinarily exercised by professionals in Bureau Veritas' profession using accepted testing methodologies, quality assurance and quality control procedures (except where otherwise agreed by the client and Bureau Veritas in writing). All data is in statistical control and has met quality control and method performance criteria unless otherwise noted. All method blanks are reported; unless indicated otherwise, associated sample data are not blank corrected. Where applicable, unless otherwise noted, Measurement Uncertainty has not been accounted for when stating conformity to the referenced standard.

Bureau Veritas liability is limited to the actual cost of the requested analyses, unless otherwise agreed in writing. There is no other warranty expressed or implied. Bureau Veritas has been retained to provide analysis of samples provided by the Client using the testing methodology referenced in this report. Interpretation and use of test results are the sole responsibility of the Client and are not within the scope of services provided by Bureau Veritas, unless otherwise agreed in writing. Bureau Veritas is not responsible for the accuracy or any data impacts, that result from the information provided by the customer or their agent.

Solid sample results, except biota, are based on dry weight unless otherwise indicated. Organic analyses are not recovery corrected except for isotope dilution methods.
Results relate to samples tested. When sampling is not conducted by Bureau Veritas, results relate to the supplied samples tested.
This Certificate shall not be reproduced except in full, without the written approval of the laboratory.
Reference Method suffix “m” indicates test methods incorporate validated modifications from specific reference methods to improve performance.
* RPDs calculated using raw data. The rounding of final results may result in the apparent difference.

==========

This report has been generated and distributed using a secure automated process.
Bureau Veritas has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per ISO/IEC 17025, signing the reports. For Service Group specific validation, please refer to the Validation Signatures page if included, otherwise available by request. For Department specific Analyst/Supervisor validation names, please refer to the Test Summary section if included, otherwise available by request. This report is authorized by Raphael Kwan, Senior Manager, BC and Yukon Regions responsible for British Columbia Environmental laboratory operations.

Duplicate: Paired analysis of a separate portion of the same sample. Used to evaluate the variance in the measurement.

Matrix Spike: A sample to which a known amount of the analyte of interest has been added. Used to evaluate sample matrix interference.

QC Standard: A sample of known concentration prepared by an external agency under stringent conditions. Used as an independent check of method accuracy.

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

(1) Method Blank exceeds acceptance limits. Sample values are >10x the concentration of the method blank and the contamination is considered irrelevant.

BUREAU VERITAS JOB #: C391810
Received: 2023/11/09, 11:40

Sample Matrix: Tissue
Samples Received: 12

Analyses	Quantity	Date Extracted	Date Analyzed	Laboratory Method	Analytical Method
Mercury in Tissue by CVAF - Wet Wt	12	N/A	2023/12/08	BBY7SOP-00012	EPA 245.7
Elements by ICPMS - Tissue Plug Wet Wt	12	2023/11/28	2023/12/01	BBY7SOP-00021 / BBY7SOP-00002	EPA 6020b R2 m
Moisture in Tissue - Freeze Drying	11	2023/11/28	2023/11/28	BBY7SOP-00021	BCMOE BCLM Aug 2014
Moisture in Tissue - Freeze Drying	1	2023/11/28	2023/11/30	BBY7SOP-00021	BCMOE BCLM Aug 2014

Remarks:

Bureau Veritas is accredited to ISO/IEC 17025 for specific parameters on scopes of accreditation. Unless otherwise noted, procedures used by Bureau Veritas are based upon recognized Provincial, Federal or US method compendia such as CCME, EPA, APHA or the Quebec Ministry of Environment.

All work recorded herein has been done in accordance with procedures and practices ordinarily exercised by professionals in Bureau Veritas' profession using accepted testing methodologies, quality assurance and quality control procedures (except where otherwise agreed by the client and Bureau Veritas in writing). All data is in statistical control and has met quality control and method performance criteria unless otherwise noted. All method blanks are reported; unless indicated otherwise, associated sample data are not blank corrected. Where applicable, unless otherwise noted, Measurement Uncertainty has not been accounted for when stating conformity to the referenced standard.

Bureau Veritas liability is limited to the actual cost of the requested analyses, unless otherwise agreed in writing. There is no other warranty expressed or implied. Bureau Veritas has been retained to provide analysis of samples provided by the Client using the testing methodology referenced in this report. Interpretation and use of test results are the sole responsibility of the Client and are not within the scope of services provided by Bureau Veritas, unless otherwise agreed in writing. Bureau Veritas is not responsible for the accuracy or any data impacts, that result from the information provided by the customer or their agent.

Solid sample results, except biota, are based on dry weight unless otherwise indicated. Organic analyses are not recovery corrected except for isotope dilution methods.
Results relate to samples tested. When sampling is not conducted by Bureau Veritas, results relate to the supplied samples tested.
This Certificate shall not be reproduced except in full, without the written approval of the laboratory.
Reference Method suffix “m” indicates test methods incorporate validated modifications from specific reference methods to improve performance.
* RPDs calculated using raw data. The rounding of final results may result in the apparent difference.

==========

Bureau Veritas has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per ISO/IEC 17025, signing the reports. For Service Group specific validation, please refer to the Validation Signatures page if included, otherwise available by request. For Department specific Analyst/Supervisor validation names, please refer to the Test Summary section if included, otherwise available by request. This report is authorized by Raphael Kwan, Senior Manager, BC and Yukon Regions responsible for British Columbia Environmental laboratory operations.

GENERAL COMMENTS

Version 2: Report reissued to include the reworked results for the following samples (2024/01/23)
MLN-HTAR-COMP-METALS-5: Lead
MLN-HTAR-COMP-METALS-8: Silver
REF-HTAR-COMP-METALS-2: Silver

Sample CED038, Elements by ICPMS - Tissue Plug Wet Wt: Test repeated.
Sample CED041, Elements by ICPMS - Tissue Plug Wet Wt: Test repeated.
Sample CED043, Elements by ICPMS - Tissue Plug Wet Wt: Test repeated.

Results relate only to the items tested.

Bureau Veritas Burnaby: 4606 Canada Way V5G 1K5 Telephone(604) 734-7276 Fax(604) 731-2386

N/A = Not Applicable

Duplicate: Paired analysis of a separate portion of the same sample. Used to evaluate the variance in the measurement.

Matrix Spike: A sample to which a known amount of the analyte of interest has been added. Used to evaluate sample matrix interference.

QC Standard: A sample of known concentration prepared by an external agency under stringent conditions. Used as an independent check of method accuracy.

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

(1) Method Blank exceeds acceptance limits. Sample values are >10x the concentration of the method blank and the contamination is considered irrelevant.

Remarks:

Bureau Veritas is accredited to ISO/IEC 17025 for specific parameters on scopes of accreditation. Unless otherwise noted, procedures used by Bureau Veritas are based upon recognized Provincial, Federal or US method compendia such as CCME, MELCC, EPA, APHA.

All work recorded herein has been done in accordance with procedures and practices ordinarily exercised by professionals in Bureau Veritas' profession using accepted testing methodologies, quality assurance and quality control procedures (except where otherwise agreed by the client and Bureau Veritas in writing). All data is in statistical control and has met quality control and method performance criteria unless otherwise noted. All method blanks are reported; unless indicated otherwise, associated sample data are not blank corrected. Where applicable, unless otherwise noted, Measurement Uncertainty has not been accounted for when stating conformity to the referenced standard.

Bureau Veritas liability is limited to the actual cost of the requested analyses, unless otherwise agreed in writing. There is no other warranty expressed or implied. Bureau Veritas has been retained to provide analysis of samples provided by the Client using the testing methodology referenced in this report. Interpretation and use of test results are the sole responsibility of the Client and are not within the scope of services provided by Bureau Veritas, unless otherwise agreed in writing. Bureau Veritas is not responsible for the accuracy or any data impacts, that result from the information provided by the customer or their agent.

Solid sample results, except biota, are based on dry weight unless otherwise indicated. Organic analyses are not recovery corrected except for isotope dilution methods.
Results relate to samples tested. When sampling is not conducted by Bureau Veritas, results relate to the supplied samples tested.
This Certificate shall not be reproduced except in full, without the written approval of the laboratory.
Reference Method suffix “m” indicates test methods incorporate validated modifications from specific reference methods to improve performance.
* RPDs calculated using raw data. The rounding of final results may result in the apparent difference.
(1) This test was performed by Bureau Veritas Bedford, Bureau Veritas Bedford, 200 Bluewater Rd. Suite 105, Bedford, NS, Canada, B4B 1G9
(2) Results are reported on an as received basis unless otherwise indicated.

==========

This report has been generated and distributed using a secure automated process.
Bureau Veritas has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per ISO/IEC 17025, signing the reports. For Service Group specific validation, please refer to the Validation Signatures page if included, otherwise available by request. For Department specific Analyst/Supervisor validation names, please refer to the Test Summary section if included, otherwise available by request. This report is authorized by Raphael Kwan, Senior Manager, BC and Yukon Regions responsible for British Columbia Environmental laboratory operations.

Duplicate: Paired analysis of a separate portion of the same sample. Used to evaluate the variance in the measurement.

Reagent Blank: A blank matrix containing all reagents used in the analytical procedure. Used to determine any analytical contamination.

Matrix Spike: A sample to which a known amount of the analyte of interest has been added. Used to evaluate sample matrix interference.

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

Surrogate: A pure or isotopically labeled compound whose behavior mirrors the analytes of interest. Used to evaluate extraction efficiency.

NC (Duplicate RPD): The duplicate RPD was not calculated. The concentration in the sample and/or duplicate was too low to permit a reliable RPD calculation (absolute difference <= 2x RDL).

VALIDATION SIGNATURE PAGE

The analytical data and all QC contained in this report were reviewed and validated by:

Phil Deveau, Scientific Specialist (Organics)

Bureau Veritas has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per ISO/IEC 17025, signing the reports. For Service Group specific validation, please refer to the Validation Signatures page if included, otherwise available by request. For Department specific Analyst/Supervisor validation names, please refer to the Test Summary section if included, otherwise available by request. This report is authorized by Raphael Kwan, Senior Manager, BC and Yukon Regions responsible for British Columbia Environmental laboratory operations.

CERTIFICATE OF ANALYSIS

BUREAU VERITAS JOB #: C391830
Received: 2023/11/09, 11:40

Sample Matrix: Tissue
Samples Received: 3

Analyses	Quantity	Date Extracted	Date Analyzed	Laboratory Method	Analytical Method
PAH in Tissue by GC/MS (SIM) (1, 2)	3	2024/01/15	2024/01/16	ATL SOP 00104	EPA 8270E R6 m

Remarks:

Bureau Veritas is accredited to ISO/IEC 17025 for specific parameters on scopes of accreditation. Unless otherwise noted, procedures used by Bureau Veritas are based upon recognized Provincial, Federal or US method compendia such as CCME, EPA, APHA or the Quebec Ministry of Environment.

All work recorded herein has been done in accordance with procedures and practices ordinarily exercised by professionals in Bureau Veritas' profession using accepted testing methodologies, quality assurance and quality control procedures (except where otherwise agreed by the client and Bureau Veritas in writing). All data is in statistical control and has met quality control and method performance criteria unless otherwise noted. All method blanks are reported; unless indicated otherwise, associated sample data are not blank corrected. Where applicable, unless otherwise noted, Measurement Uncertainty has not been accounted for when stating conformity to the referenced standard.

Bureau Veritas liability is limited to the actual cost of the requested analyses, unless otherwise agreed in writing. There is no other warranty expressed or implied. Bureau Veritas has been retained to provide analysis of samples provided by the Client using the testing methodology referenced in this report. Interpretation and use of test results are the sole responsibility of the Client and are not within the scope of services provided by Bureau Veritas, unless otherwise agreed in writing. Bureau Veritas is not responsible for the accuracy or any data impacts, that result from the information provided by the customer or their agent.

Solid sample results, except biota, are based on dry weight unless otherwise indicated. Organic analyses are not recovery corrected except for isotope dilution methods.
Results relate to samples tested. When sampling is not conducted by Bureau Veritas, results relate to the supplied samples tested.
This Certificate shall not be reproduced except in full, without the written approval of the laboratory.
Reference Method suffix “m” indicates test methods incorporate validated modifications from specific reference methods to improve performance.
* RPDs calculated using raw data. The rounding of final results may result in the apparent difference.
(1) This test was performed by Bureau Veritas Bedford, Bureau Veritas Bedford, 200 Bluewater Rd. Suite 105, Bedford, NS, Canada, B4B 1G9
(2) Results are reported on an as received basis unless otherwise indicated.

==========

This report has been generated and distributed using a secure automated process.
Bureau Veritas has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per ISO/IEC 17025, signing the reports. For Service Group specific validation, please refer to the Validation Signatures page if included, otherwise available by request. For Department specific Analyst/Supervisor validation names, please refer to the Test Summary section if included, otherwise available by request. This report is authorized by Raphael Kwan, Senior Manager, BC and Yukon Regions responsible for British Columbia Environmental laboratory operations.

Reagent Blank: A blank matrix containing all reagents used in the analytical procedure. Used to determine any analytical contamination.

Matrix Spike: A sample to which a known amount of the analyte of interest has been added. Used to evaluate sample matrix interference.

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

Surrogate: A pure or isotopically labeled compound whose behavior mirrors the analytes of interest. Used to evaluate extraction efficiency.

(1) Matrix Spike: < 10 % of compounds in multi-component analysis in violation.

8.0 NON-INDIGENOUS SPECIES/AQUATIC INVASIVE SPECIES (NIS/AIS)

This chapter presents the results of the Non-Indigenous Species (NIS) and Aquatic Invasive Species (AIS) monitoring program as a part of the larger Marine Environmental Effects Monitoring Program (MEEMP) conducted at Milne Port and in Milne Inlet during the 2023 open-water season. This monitoring component was developed to achieve the requirements outlined in the Project Certificate (PC) Conditions described in Chapter 1.0, Table 1-2, and specifically PC Conditions No. 76, 87, 89, 91, 99 (a), and 99 (c).

8.1.1 Objectives

The MEEMP objectives are outlined in Section 1.3 for the overall program. The objectives specific to the NIS/AIS monitoring program include the following:

- Sample marine environment to screen for potential Project-related introductions of taxa that are invasive or non-indigenous.
- Update taxonomic inventory of marine biota (i.e., list of organisms observed) for Milne Inlet.
- Communicate outcomes for specimens sent for independent verification.

8.1.2 Definitions

Definitions are provided below for technical terms used throughout this chapter. Definitions are written to align with federal and international standards, based on the Convention of Biological Diversity Decision VI/23 (CBDD) and Invasive Alien Species Strategy for Canada (Government of Canada 2004).

Aquatic invasive species (AIS): harmful non-indigenous species whose introduction or spread threatens the environment, the economy, or society (Government of Canada 2004).

cf.: “compare with”, in taxonomy refers to a taxonomic designation that indicates an inexact match to the indicated taxon. The specimen may represent a similar related species, an undescribed morph, or the specimen may be lacking characteristics (due to damage, lack of development of the features, or immaturity) that allow for a positive identification.

Cryptogenic: a species that is not demonstrably native or introduced, a species with an obscure or unknown natural range (Carlton 1996).

forma (f.): or form, indicating a secondary rank classification that designates a group with a noticeable morphological deviation.

Homotypic synonym: where there is more than one species name on record based on the same type taxon or species description. May occur when the taxon is independently described by separate taxonomists, or when species are moved from one genus to another.

indet.: “indeterminate”, used to indicate the specimen can be identified only to the listed taxonomic level, used for indeterminate taxonomic designations above genus. This is typically used for samples that were damaged, juvenile, or missing features preventing a conclusive identification beyond the indicated taxonomic level.

Non-indigenous species (NIS): species introduced by human action outside their natural past or present distribution (Government of Canada 2004).

sp.: "Species", used to indicate the species name is indeterminate. This is typically used for samples identifiable to genus that were damaged, juvenile, or missing features preventing a conclusive identification to species level.

sp. nr.: "species near", similar to "cf.", but representing a species that is similar to the described species, however there are indications that the species is not a correct match. This may occur in poorly or newly described taxonomic groups where a specimen clearly matches the genus description but does not necessarily match the described species within it. May indicate a species that is new to science and lacks a description on record.

Other terms used throughout the report include the following:

Flagged taxa: Taxa are flagged where there is low confidence in their identifications, uncertainties in the range on record, or presence on any of the AIS databases.

High risk: A species is considered "High Risk" if it is:

- not reported to be present in the Canadian Arctic
- capable of using shipping vectors
- listed as an AIS in other areas
- well-documented to have potentially serious invasive behaviours elsewhere, and/or showing invasive behaviours in Milne Inlet

Low risk: A species is considered "Low Risk" if it is:

- not reported to be present in the Canadian Arctic or there is low certainty as to its presence, or identity is uncertain, or taxon is undergoing natural range expansion
- not listed on AIS databases, or (in the case of higher taxon identification, with one or more representative species listed on an AIS database) the representative species is/are unlikely to establish in the Arctic (e.g., tropical/subtropical)

Moderate risk: A species is considered "Moderate Risk" if it is:

- not reported to be present in the Canadian Arctic
- capable of using shipping vectors
- listed as an AIS in other areas, but has shown no invasive behaviours in Milne Inlet

No risk: A species is considered "No Risk" if it is:

- reported to be present in the Canadian Arctic (or, its distribution in waters adjacent to the Canadian Arctic provides high certainty that its range includes the Canadian Arctic), prior to Project operations or in areas outside the Project's area of influence
- not listed on AIS databases, or if listed it is native to Canadian Arctic or (in the case of higher taxon identification, with one or more representative species listed on an AIS database) the representative species is/are unlikely to establish in the Arctic (e.g., tropical/subtropical)

Trigger List: a list of High-Risk taxa that are showing invasive behaviour in Milne Inlet or have shown invasive behaviour in similar ecosystems. Responsive actions will be species specific and proportional to the risk. There are currently no species on the Trigger List and, therefore, no species-specific response or action plans have been developed to date. Should a species be added to the Trigger List, a species-specific response plan would be developed in consultation with Fisheries and Oceans Canada (DFO).

Watch List: a list of taxa identified in Milne Inlet that are subject to a heightened level of monitoring, which may include targeted sampling for DNA analysis or population assessment. Taxa on this list may be considered to be Low Risk, Medium Risk or High Risk.

8.2 Study Design

NIS/AIS monitoring is conducted annually. Annual monitoring increases the data available for Milne Port, and is also important from a regional perspective, as this program currently represents the most intensive sampling for NIS/AIS in the Canadian Arctic and has contributed to filling regional data gaps on biodiversity.

The NIS/AIS monitoring program is designed to detect potential introductions of non-indigenous and/or invasive species from potential Project-related vectors such as ballast water discharges or ship hull biofouling. Since ballast water releases only occur at the anchorages and the Ore Dock in Milne Port, sampling conducted to date has largely focused on southern Milne Inlet as the area with highest likelihood of a potential marine invasion.

NIS/AIS monitoring involves a combination of dedicated surveys as well as screening all specimens caught during surveys for all MEEMP components.

Dedicated surveys (Figure 8-1) conducted for the NIS/AIS program involve the following:

i) Sampling zooplankton at Milne Port and at Ragged Island

ii) Recruitment surveying using settlement substrates deployed around Milne Port and at Ragged Island

iii) Collecting benthic infauna at four stations near the anchorage location at Ragged Island.

Specimens collected during the following MEEMP components (Figure 8-2) are screened for the NIS/AIS monitoring program:

i) Benthic infaunal survey (Chapter 4.0)

ii) Epifaunal and macroalgal survey (Chapter 5.0)

iii) Fish community survey (Chapter 6.0)

iv) Fish health survey (i.e., taxa found in fish stomachs, fish parasites) (Chapter 7.0).

NIS/AIS monitoring therefore involves data collection across multiple trophic levels – marine vegetation, invertebrates, zooplankton, and fish – to establish a comprehensive inventory of existing marine biota in the Project area that serves as a point of reference for any new species/taxa identified (herein referred to as the “Milne Inlet Taxonomic Inventory”). The Milne Inlet Taxonomic Inventory was initially populated with the list of organisms identified during baseline studies in 2008 through 2014, and has been updated annually since 2015 with new records collected during MEEMP surveys.

8.2.1 Modifications to the Program (2023)

Several modifications were made to the sampling program due to logistical limitations that arose during field work (see Chapters 4.0 and 5.0), as well as some new monitoring commitments. Sampling locations used for the 2023 NIS/AIS monitoring program are shown in Figure 8-1 (dedicated surveys) and Figure 8-2 (MEEMP components).

The 2023 benthic infaunal program (Chapter 4.0) was intended to collect samples from the full-scale benthic community radial sampling design consisting of 60 stations[1], however, due to limitations during field work, sample collection only occurred at 41 of these stations. Sampling was spaced along the radial transects to increase coverage throughout Milne Port, with greater emphasis on stations adjacent to the Ore Dock. Additionally, four benthic infauna stations at Ragged Island specific to the NIS/AIS program that were planned for sampling in 2023 could not be completed.

Additional benthic infauna samples, not part of the radial sampling design, were collected in 2023 after Baffinland committed to monitoring sediment and benthic infauna for scouring effects potentially associated with the use of large (Baby Cape and Capesize) ore carriers. This monitoring is to occur for three years after the initial use of the large ore carriers (Chapters 3.0 and 4.0). Two new stations (SCV-1 and SCV-2) were established to the west of the Ore Dock (see “Capesize Station Only” on Figure 3-2). A previously established station (SE-18-1), that was not part of the radial sampling design, was also sampled for Capesize effects monitoring. With this sampling added to the benthic radial sampling design, a total of 44 benthic stations were screened for occurrence of potential NIS/AIS in 2023.

Logistical issues also limited the number of quadrats that were surveyed by divers for the epifauna and macroalgae sampling to 18 of the 26 quadrats (Chapter 5.0). Settlement substrates co-located with quadrats that could not be surveyed were also not sampled in 2023.

Program delays and time constraints in 2021 and 2022 had prevented collection of annual settlement substrates on the planned schedule at several stations. These substrates were collected in 2023 to align the program with the intended rotation. As these substrates were deployed for longer than a year, they were not representative of annual recruitment and were instead preserved as a source of additional DNA samples.

Zooplankton sampling was increased from a single collection event to three events over the open water season to capture variability in zooplankton populations. Six oblique (horizontal) and six vertical zooplankton samples were collected in Milne Port during each collection event. The zooplankton collection event planned for Ragged Island could not be conducted due to ice cover and delays to the program.

A collaboration with the research laboratory of Dr. Gary Saunders at the University of New Brunswick to conduct a study of macroalgae collected during Baffinland’s monitoring programs commenced in 2023. All macroalgae collected during MEEMP and NIS/AIS field programs are being provided to Dr. Saunders for identification by molecular and/or microscopic taxonomic methodologies, as appropriate. Archived specimens from previous years of monitoring will also be reviewed.

[1] The monitoring frequency of the benthic infauna sampling program is every 3 years, as multiple years of monitoring data have revealed no adverse trends in benthic community indicators related to Project construction and operations, and for consistency with routine biological sampling for other mining effects monitoring programs (e.g., the federal Environmental Effects Monitoring Program [EEM]). In the years when the full benthic infauna sampling program is not conducted, a smaller number of samples is collected. See Chapter 4.0 for full description of the program.

8.2.2 Indicators and Thresholds

The NIS/AIS monitoring program was initially designed as a surveillance survey but over time has developed into an adaptive NIS/AIS management process. The process described below has been adjusted to align with terminology in Baffinland's Trigger Action Response Plan (TARP) (Baffinland 2021; Baffinland 2023).

The performance indicator of this program is "occurrence of an NIS/AIS in the Milne Inlet environment". Detection of a new taxonomic record that could potentially represent introduction of an NIS or AIS will initiate a response protocol aimed to assess the risk and determine the appropriate course of action.

Terminology for risk categories used in the NIS/AIS monitoring program has been updated since the 2022 MEEMP report (WSP 2023). The former risk categories for the NIS/AIS Monitoring Program were Low Risk / High Risk / Trigger List, but these have now been renamed to align with the risk categories used for other indicators in the TARP. Levels of risk are now named No Risk / Low Risk / Moderate Risk / High Risk.

Details of the risk condition categories, thresholds and pre-defined responses are presented in section 8.3.3.1.

8.3 Materials and Methods

8.3.1 Sample Collection for Taxonomic Identification

Sampling for the 2023 MEEMP and NIS/AIS monitoring programs was conducted between 20 July and 21 August by a field team composed of eight WSP biologists including biologist/SCUBA divers, a BIM vessel operator, and two local Inuit field technicians from Pond Inlet, NU (BIM employees). Sampling was conducted from a 9.1-m aluminum vessel (research vessel) in addition to two inflatable tender vessels (6.1 m and 4.9 m) based at the Milne Port facility. Additional sampling for zooplankton was performed by Baffinland's environmental technicians during September.

8.3.1.1 Benthic Infauna, Macroflora and Benthic Epifauna, Fish and Incidentals

Screening to determine NIS/AIS status was conducted for all specimens caught or observed during surveys for MEEMP components, including benthic infaunal and epifaunal invertebrates (Chapter 4.0 and Chapter 5.0, respectively), macroflora (Chapter 5.0), fish species (Chapter 6.0), fish parasites and taxa found in fish stomachs (Chapter 7.0). Methodologies for these collections are described in the respective chapters of this report.

Incidental samples were also collected opportunistically during SCUBA surveys for macroflora and epifauna as well as during fishing efforts. Specimens of all collected incidental taxa were preserved in 10% formalin and submitted to Biologica Environmental Services Ltd. (henceforth referred to as "Biologica"; a Canadian marine and freshwater taxonomy laboratory) for taxonomic identification.

8.3.1.2 Settlement Substrates

Settlement substrates deployed from 2020 to 2022 in various locations throughout Milne Port were sampled in 2023 to monitor for recruitment of fouling taxa. Stations were located between -3 and -12 m water depth, along the east, north, and west faces of the Freight Dock as well as various depths co-located with the quadrats for epifauna and macroalgal monitoring (Figure 8-1, Table 8-1, Chapter 5.0). Three stations situated at the Ragged Island anchorage were not sampled in 2023 due to logistical constraints.

Each station was configured as three to five settlement baskets filled with locally sourced cobble and three to five settlement plates (each comprised of a 20 L plastic bucket lid oriented horizontally) attached to a line with a subtidal buoy (Figure 8-3). Settlement baskets and plates are sampled on annual and multi-year (ideally, three-year) schedules. Sampling involved retrieval of one settlement basket and one settlement plate that was deployed for three years, and their replacement with a clean settlement basket and plate. In subsequent years, the next settlement basket and plate in the series will be collected, which will have been deployed for three years to represent short to medium term colonization. An additional plate and basket were collected annually and replaced with a new plate and basket to represent immediate term colonization.

The first settlement substrates were deployed in 2020 at the Freight Dock and quadrats Q1-Q10. Due to supply chain limitations associated with COVID-19 in 2020, the addition of new stations in 2021, and the loss of some sampling locations in 2021 and 2022, full sets of annual and multi-year plates and baskets were not available for all stations. Deployment year and soak time at recovery for all settlement substrates recovered in 2023 are described in Table 8-1.

Plates were cut underwater to detach from the center line and placed within a collection bag and brought to the surface where they were placed in a clean sandbag with ambient water (to separate samples) and then placed in a tote of water. An internal label was created for each sample and added to the containers for later identification. The plates were photographed prior to being cut into quarters using a knife and then placed in a 4 L sample bucket.

Baskets were brought to the surface and placed in clean 4 L buckets with ambient water. The cobbles were removed from the basket and photographed prior to being placed into a 4 or 8 L sample bucket. As possible, visible macroalgae were removed with forceps and placed into labelled vials with silica gel for genetic and microscopic identification at the University of New Brunswick (Dr. Gary Saunders).

Samples were preserved with 10% formalin. The buckets were sealed and inverted several times to promote homogenization with the formalin. The buckets were labeled internally and externally with water-resistant labels and sent to Biologica for taxonomic analysis of attached and motile invertebrates. Macroalgae were removed from the sample by Biologica and will be sent to the University of New Brunswick for taxonomic analysis.

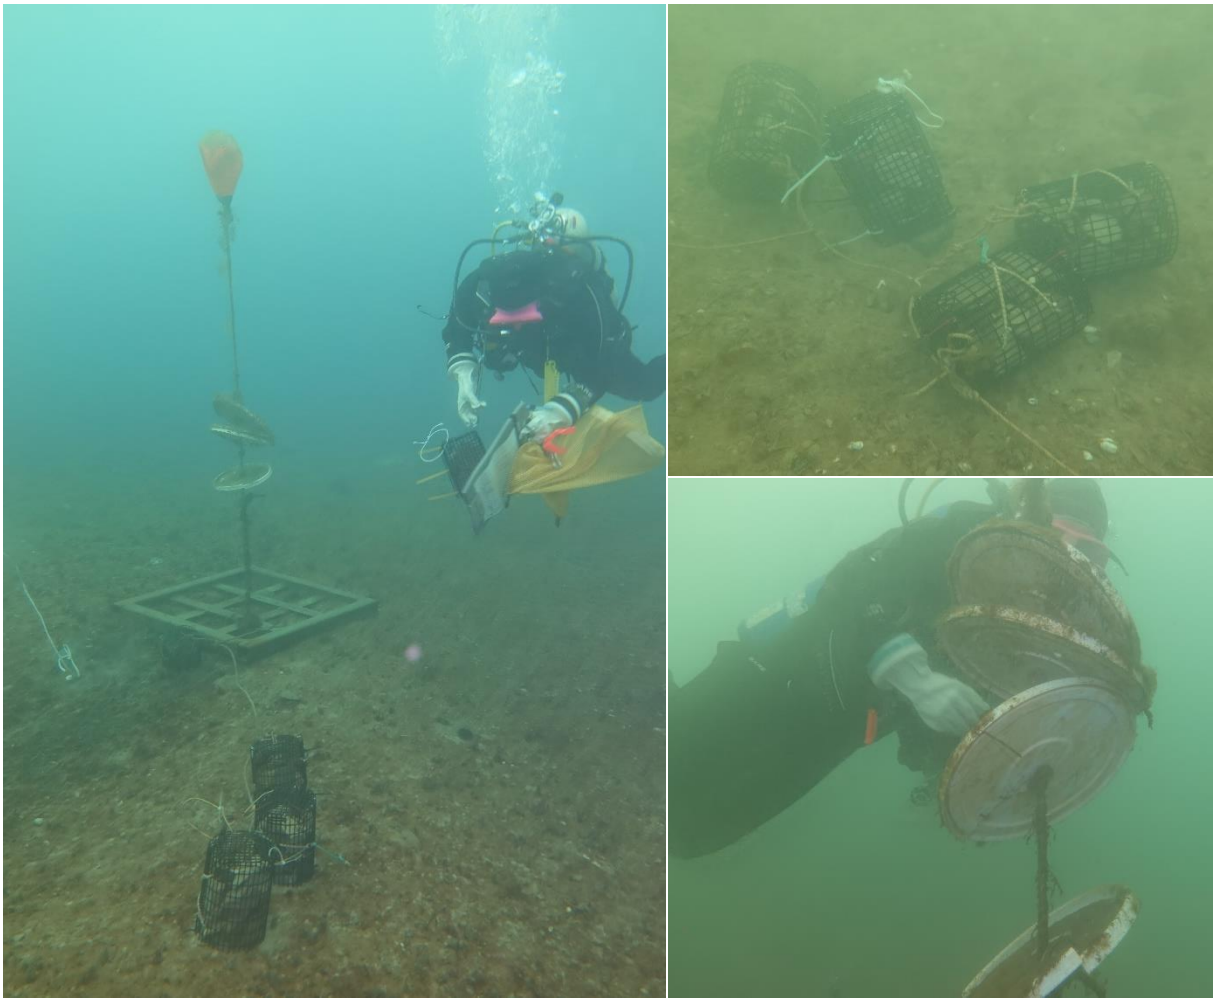

Figure 8-3: Quadrat settlement baskets and plates at Q4, settlement baskets from Q11, and settlement plates being retrieved from Q1.

[1]West M and D Stations were co-located.

[2]No annual substrates were collected at Centre M and Centre D as they were not replaced in 2022.

[3]Centre D Station was moved shallower in 2023.

[4] Two baskets were lost off East M Station in 2022 when the station moved from its original location into deeper water. New baskets were added in 2023 as replacements.

[5] Due to program timing issues, these quadrats' settlement substrates were not able to be recovered in 2023.

[6] Q10 plate was out of sync due to not being collected in 2022.

[7] Q16 had moved to deeper depths in 2022 due to vessel anchor dragging and due to program timing issues, could not be redeployed or sampled in 2023.

8.3.1.3 Zooplankton

Zooplankton samples were collected using vertical and horizontal oblique tows over three sampling events at the beginning, middle, and end of the open water season (Figure 8-1, Table 8-2). Vertical hauls were conducted at six sampling stations in Milne Port by lowering a 0.3 m diameter (64 µm mesh size) plankton net to a depth of 1 m to 3 m above the bottom and then raising the net by hand to the surface at a rate of approximately 1 m/s (visually estimated). Three replicate hauls were conducted at each station and combined into a single composite sample following methodology from previous years (WSP 2023).

Oblique tows were conducted by towing a 0.5 m diameter net (250 µm mesh size) for a period of 10-12 minutes per tow. The net was towed in a sinusoidal fashion by means of regular transitions in tow speed (1-minute towing at a speed of 8-10 km/h, 1-minute idling), which allowed the weighted net to periodically sink and rise during active sampling. This helped avoid sampling only in the upper few metres of the water column. The sinusoidal oblique tow approach and larger mesh size is used to help catch a more representative sample of larger zooplankton in the water column and to catch faster moving larvae (e.g., fish larvae, larger crustaceans) than is possible with the vertical tow method. Where required, transects were towed in sections to allow for clearing of the plankton net, and samples were carefully flushed into a sample container as a single composite sample for each transect.

Once the sample was transferred to the sample container, ambient seawater was splashed or sprayed on the outside of the net to rinse any remaining sample into the container. Between each tow, the nets and bottles were rinsed (either flushed with sea water or by using a spray bottle filled with sea water through the net mesh to exclude organisms). All zooplankton samples were preserved in 5% formalin and submitted to Biologica for taxonomic identification. Laboratory methodologies are detailed in Appendix 8D-3.

[1]Waypoints for horizontal oblique tows are targeted coordinates. Actual survey track varied between each survey event.

8.3.2 Samples Collected for Genetic Analysis

In 2023, targeted benthic infaunal sampling occurred at six stations in Milne Port where potential high-risk taxa that were placed on the program Watch List had been collected in previous years (Table 8-3).

Table 8-3: Benthic Stations Selected for DNA Barcoding and Targeted Taxa (Putative Identifications)

Station	UTM Coordinates (17W)		Taxa of Interest
	Easting	Northing	
SW-2	503064	7976526	*Marenzelleria* sp.
SW-12	502037	7976473	*Marenzelleria* sp. *Ampharete petersenae*
SW-13	501920	7976428	*Marenzelleria* sp. *Ampharete petersenae*
SE-1	503907	7976727	*Paramphitrite/Amphitrite birulai* *Ampharete petersenae*
SNE-7	504189	7977629	*Oncousoecia* sp. *Sosane wireni*
SNE-10	504364	7978043	*Oncousoecia* sp. *Sosane wireni*

These samples were collected and processed in a manner similar to the other benthic infauna samples (Chapter 4.0), however, the samples were preserved in 95% ethanol, rather than formalin, to allow for DNA analysis should specimens resembling the flagged taxa be identified.

All benthic infauna samples collected for DNA analysis were sorted by Biologica following the same procedures for benthic infauna samples. Targeted taxa, if present in the samples, were removed to separate vials to be sent for barcoding. Targeted taxa included potential NIS/AIS species that were placed on the Watch List after being flagged in previous surveys and included other potential invasive taxa for Nunavut compiled from a high-risk species brochure (Government of Nunavut 2016).

Settlement substrates that were otherwise not required for 2023 sampling were preserved as a source of additional DNA samples (Table 8-4). Substrates that were not required included annual and multi-year substrates that were not collected in 2022 due to time constraints and represented a two-year deployment time or were extraneous to the substrates already collected at those stations (e.g., the multi-year plate from 2022 where the multi-year plate from 2023 was already collected). A subset of plate samples was archived for future DNA analysis and processed in a similar manner to other settlement substrate samples (Section 8.3.1.2); however, the plate pieces belonging to the same station were placed within a tube of nylon netting and tied to contain organisms and prevent cross-contamination with other samples. These samples are referred to as ‘preserved whole’ samples (Table 8-4). Samples from multiple stations were then added to one 8 L bucket and preserved with 95% ethanol. The remaining DNA sample substrates were ‘scraped’ (Table 8-4) as follows:

- Identifiable larger epifauna taxa were picked off the substrate and added to 52 mL vials and preserved with 95% ethanol. These samples, and “preserved whole” samples were reviewed by Biologica for target taxa (as described above). Additionally, to help address difficulties in monitoring for introductions of biofouling organisms and to further build the taxonomic inventory, specimens from encrusting-type taxa (i.e., tunicates and bryozoans) or difficult to identify taxa were selected for DNA analysis. Morphological identification prior to preparation for DNA analysis was only performed on large or robust specimens to prevent the loss of viable material.
- Macroalgae was separated, when possible, by taxonomic group (brown, red and green algae if identifiable) and placed in labelled 1.5 mL centrifuge tubes with silica gel. These samples were sent to the University of New Brunswick for microscopic and genetic identification.
- The remainder of the sample was scraped with a paint scraper into 52 mL vials and preserved with 95% ethanol. These samples were archived. Future analysis of these samples may include targeted analysis for sequences of interest, or broader meta-barcoding.

Whole specimen or tissue samples of taxa sent for DNA verification, other than macroalgae, will be sent to the Canadian Centre for DNA Barcoding (CCDB) at the University of Guelph for barcoding. Macroalgae will be sent to the University of New Brunswick for barcoding.

Table 8-4: Settlement Substrates Collected for Genetic Analysis

Station	Substrate Sample Collected	Preservation Method	Preservative
Centre M	Annual Plate	Preserved whole	Ethanol (95%)
	Annual Basket	Scraped	Ethanol (95%)
Centre D	Annual Plate	Scraped	Silica Gel Ethanol (95%)
	Multi-year Basket	Scraped	Ethanol (95%)
Q10	Multi-year Plate	Preserved whole	Ethanol (95%)
Q11	Multi-year Basket	Scraped	Ethanol (95%)
	Multi-year Plate	Scraped	Ethanol (95%)
Q12	Multi-year Basket and Plate	Scraped	Ethanol (95%)
Q13	Multi-year Plate	Scraped	Ethanol (95%)
	Multi-year Basket	Scraped	Silica Gel Ethanol (95%)
Q14	Multi-year Basket	Scraped	Ethanol (95%)
Q15	Multi-year Basket	Scraped	Ethanol (95%)
	Multi-year Plate	Preserved whole	Ethanol (95%)
Q17	Multi-year Basket	Scraped	Ethanol (95%)
	Multi-year Plate	Preserved whole	Ethanol (95%)
Q18	Multi-year Basket and Plate	Scraped	Ethanol (95%)
Q19	Multi-year Basket	Scraped	Silica Gel Ethanol (95%)
	Multi-year Plate	Scraped	Ethanol (95%)
Q20	Multi-year Basket	Scraped	Ethanol (95%)
	Multi-year Plate	Preserved whole	Ethanol (95%)

8.3.3 Data Analysis

8.3.3.1 Risk Condition Categories, Thresholds, and Responses

As stated in section 8.2.2, the terminology used in the 2023 NIS/AIS monitoring program has been updated from the 2022 MEEMP report (WSP 2023). Levels of risk are now defined as No Risk / Low Risk / Moderate Risk / High Risk.

Definitions of the risk condition categories, thresholds, and pre-defined responses are as follows (Table 8-5):

Table 8-5: Risk Condition Categories and Responses to Detections of New Taxa Records in the NIS/AIS Monitoring Program

(a) No Risk

Description of Risk Condition	Response
Taxon was previously reported in Canadian Arctic prior to Project operations, and/or in the Canadian Arctic outside of the Project's area of influence[2]. AND The identified species or representative species[3] of the taxon are not listed in an Aquatic Invasive Species database.	Taxon is added to the taxonomic inventory for Milne Inlet.
OR	
Taxon was reported in Canadian Arctic prior to Project Operations and/or in the Canadian Arctic outside of the Project's area of influence[4]. AND Species or representative species are listed in an Aquatic Invasive Species database but the native range (or range prior to Project operations) includes the Project area OR targeted literature review has determined that the AIS-listed species (including representative species) is unlikely to establish in the ecosystem conditions of the Project area. AND Targeted literature review of the taxon has determined low likelihood of identification matching the list of known AIS and/or low likelihood of establishment of the listed AIS in the Project area.	Targeted literature review is conducted. Taxon is added to the taxonomic inventory for Milne Inlet.

[2] Area of influence is considered to include Milne Inlet and areas potentially influenced by Project shipping routes (including, but not limited to, areas of Baffin Bay and Eclipse Sound).

[3] Representative species are used in the case where identification of a collected organism to the species level has not been possible. If, at the level to which the organism is identifiable, any species in the taxon are listed in an invasive species database, a targeted literature review will be conducted for all listed species (i.e., these listed species are considered representative species for this taxon).

[4] Area of influence is considered to include Milne Inlet and areas potentially influenced by Project shipping routes (including, but not limited to, areas of Baffin Bay and Eclipse Sound).

(b) Low Risk

Description of Risk Condition	Response
At least one of the following must be met. Taxon is not reported as present in Canadian Arctic or there is low certainty as to its presence. OR There is low confidence in the identification (includes species pending verification), where related species are listed in AIS databases and there is potential for survival in the Project area. OR Taxon is undergoing range expansion into Milne Inlet that is attributed to factors or vectors unrelated to Project shipping (e.g., climate change).	Specimens are sent for independent taxonomic verification, and if possible, DNA analysis. Targeted literature review of the taxon (when first detected, and updated in subsequent years when taxon is detected). Ongoing monitoring, including routine sampling in MEEMP with attention to areas where the taxon was previously detected, to determine if it is established in Milne Inlet, and detect any indicators of invasive behaviour (e.g., from community metrics and distribution data). Taxon is added to Project Watch List. The risk status of the taxon will be reassessed each year it is detected.

(c) Moderate Risk

Description of Risk Condition	Response
Taxon is not reported as present in Canadian Arctic. AND Taxon is capable of using shipping vector(s). AND Taxon is listed as an AIS in other locations. AND Taxon is not yet confirmed to show those behaviours in Milne Inlet.	Specimens are sent for independent taxonomic verification, and if possible, DNA analysis. Targeted literature review (when first detected and repeated annually, even if not detected in that year). Heightened monitoring (i.e., annual targeted sampling at sites where taxon has been previously observed, to monitor for changes in community metrics and distribution data). Taxon is added to Project Watch List. The risk status of the taxon will be reassessed each year it is detected

(d) High Risk

Description of Risk Condition	Response
Taxon is not reported as present in Canadian Arctic. AND Taxon is capable of using shipping vector(s). AND Taxon is listed as an AIS in other locations. AND <u>At least one of the following</u> Taxon or closely related species has well-documented and potentially serious invasive behaviours (e.g., habitat disruption or displacement of native species) in other areas. OR Taxon shows evidence of invasive behaviour in Milne Inlet including but not limited to the species dominating the relative abundance, or reductions in species diversity and richness at sites where the species occurs; competition or predation on native taxa; habitat destruction; and/or dispersal/establishment from site of initial detection.	Specimens are sent for independent taxonomic verification, and if possible, DNA analysis. Targeted literature review (when first detected and repeated annually, even if not detected in that year). Heightened monitoring (i.e., annual targeted sampling at sites where taxon has been previously observed, to monitor for changes in community metrics and distribution data). The risk status of the taxon will be reassessed each year even it is not detected. Taxon is added to Project Watch List and is considered for addition to Trigger List. Taxon will be added to Trigger List if it shows invasive behaviours in Milne Port. Addition to the Trigger List triggers development of a Rapid Response Plan for the taxon, to be determined in consultation with DFO in accordance with the most updated version of Canadian Rapid Response Framework for Aquatic Invasive Species (i.e., updates to Locke et al. 2011).

8.3.3.2 Detection

Data analysis focused on taxa presence, rather than enumeration. Should a potential NIS/AIS be detected, relative abundance and related metrics will be examined as part of heightened monitoring.

All specimens except for macroalgae were initially sent to Biologica for taxonomic identification, with specimens identified to the lowest possible taxonomic level. Macroalgal specimens removed from samples sorted by Biologica or those sorted in the field will be sent to the University of New Brunswick for identification.

Detection involved screening the taxonomic list received from annual survey efforts against the Milne Inlet Taxonomic Inventory (all taxa observed across all baseline and monitoring surveys) to identify new records (taxa that have not been observed previously) and taxa that have been previously flagged for heightened monitoring which would require an updated review. Taxa are subjected to a process of investigation to assess risk as outlined in Table 8-5.

8.3.3.3 Literature Review

Taxa were assessed further through literature review to determine if their known distributions and ranges included North Atlantic, Arctic and/or Canadian Arctic waters, whether the taxon had a history as an AIS somewhere else in the world, and to check for changes in the taxonomic nomenclature. The Milne Port Taxonomic Inventory was updated to include any new or updated accepted species names for any previously identified species.

Information on general species biology and distributions for the literature review was sourced from the following:

- World Register of Marine Species (WoRMS 2024)
- Global Biodiversity Information Facility (GBIF 2024)
- Encyclopedia of Life (EOL 2024)
- SeaLifeBase (Palomares and Pauly 2023)
- National Centers for Coastal Ocean Science (NCCOS 2023)
- Arctic Register of Marine Species (ARMS) compiled by the Arctic Ocean Diversity (ArcOD 2023, Sirenko et al. 2024)
- Arctic species inventories published or accessed through the Ocean Biogeographic Information System (UNESCO 2024)

In addition, specimens were also compared against the following global and domestic AIS databases and resources:

- Global invasive species database (Molnar et al. 2008)
- National Exotic Marine and Estuarine Species Information System (NEMESIS; Fofonoff et al. 2018)
- Global Invasive Species Database (GISD) published by the IUCN Invasive Species Specialist Group (ISSG 2024)
- Known invasive species list within the National Risk Assessment for Introduction of Aquatic Nonindigenous Species to Canada by Ballast Water (Casas-Monroy et al. 2014)
- High-risk AIS in the Hudson Bay Region and Canadian Arctic identified using the Canadian Marine Invasive Screening Tool (CMIST) (Goldsmit et al. 2021)
- World Register of Introduced Marine Species (WRIMS; Costello et al. 2024)
- Invasive Species Compendium published by CABI (Centre for Agriculture and Bioscience International; CABI 2024)
- AquaNIS information system on aquatic non-indigenous and cryptogenic species (CRPI 2024)
- The Arctic Invasive Alien Species: Strategy and Action Plan developed by CAFF (Conservation of Arctic Flora and Fauna) and PAME (Protection of the Arctic Marine Environment) (CAFF and PAME 2017)
- Regional specific invasive species Watch List informational brochure (Government of Nunavut 2016).

8.3.3.3.1 Distribution Categories

Based on the range on record for each taxon, a value was assigned to each new observation to express the distance to the closest record as a descriptor of distribution. Methods for describing the distribution categories followed those of Goldsmit et al. (2014), adjusted for the Project location (Figure 8-4). Each taxon was assigned a value of 1 to 5 based on the locations of the closest records to the project area, where:

- A value of 1 indicated there were previous records "Within the Region". The region was defined as Milne Inlet between the Milne Port Site and Ragged Island[5].
- A value of 2 indicated that there was no record within the immediate region, however there was a record from the "Surrounding Region". Boundaries for the surrounding region included the Eastern Canadian Arctic and Davis Strait.
- A value of 3 indicated that records existed for the taxon in other regions of the Canadian Arctic, or "Arctic Outside Region". Boundaries included the Western Canadian Arctic and Hudson Bay.
- A value of 4 indicated the taxon had a "Circumpolar/Circumboreal Distribution" on record, indicating the taxon was recorded in other locations within the Arctic, or had a generally described Arctic distribution, with no georeferenced collections in the Arctic Outside Region.
- A value of 5 indicated the taxon had a "Wider Distribution" on record that did not clearly include records within circumpolar or circumboreal regions.

Supporting information on distribution for each taxon (as requested by MEWG members) was summarized by indicating the closest Marine Ecoregions of the World (MEOW; Spalding et al. 2007) where specimens had been recorded in the scientific literature or databases listed above. Based on biology or ecosystem connectivity, species in nine Arctic ecoregions listed below were considered to have a reasonable probability of having a natural range that would include Milne Port. All ecoregions represent coastal and shelf waters shallower than 200 m, with seaward boundaries extending 370 km (200 nautical miles) offshore or to 200 m depth (whichever is further offshore). Relevant Arctic Ecoregions applicable to MEEMP surveys are as follows (in approximate order of proximity to the Project area):

- **Baffin Bay–Davis Strait** – Davis Strait north of Cape Dyer to the northern extent of Baffin Bay, including the eastern extent of Lancaster Sound. Milne Port is located within this ecoregion. This ecoregion falls within the boundaries of distribution categories 1 and 2.
- **Lancaster Sound** – The Lancaster Sound region of the southern Arctic Archipelago, including Devon Island, Sommerset Island, Cornwallis Island, as well as the eastern and southern coastlines of Prince of Wales Island and Bathurst Island. This ecoregion falls within the boundaries of distribution categories 1, 2 and 3.
- **High Arctic Archipelago** – The Arctic Archipelago north of Lancaster Sound and Viscount Melville Sound. This ecoregion falls within the boundaries of distribution categories 2, 3 and 4.
- **Northern Labrador** – Northern Labrador Sea at Davis Inlet to Southern Davis Strait at Cape Dyer, including the eastern extent of Hudson Strait. This ecoregion includes Iqaluit and Frobisher Bay. This ecoregion falls within the boundaries of distribution categories 2 and 4.

[5] Due to the limited number of species surveys that have occurred in this region in comparison to MEEMP survey efforts, it is anticipated that most new observations in the program will not fall into this category.

- **Hudson Complex** – Includes the waters of Hudson Bay, James Bay, Hudson Strait, and Foxe Basin, as well as the eastern extent of Fury and Hecla Strait. This ecoregion falls within the boundaries of distribution category 3.
- **West Greenland Shelf** – Coastal and shelf waters of Western Greenland approximately between Cape York and Nûk. This ecoregion falls within the boundaries of distribution categories 2 and 4.
- **North Greenland** – Coastal and shelf waters of North Greenland approximately between Cape York and Danmarkshavn. This ecoregion falls within the boundaries of distribution categories 2 and 4.
- **East Greenland Shelf** – Coastal and shelf waters of North Greenland approximately between Danmarkshavn and Nûk. This ecoregion falls within the boundaries of distribution category 4.
- **Beaufort–Amundsen–Viscount Melville–Queen Maud** – The southern Arctic Archipelago west of the Lancaster Sound ecoregion, extending west past Cape Perry. This ecoregion falls within the boundaries of distribution category 3.

An uncertainty value was also provided to indicate the confidence in the available data used to place the specific taxon within the appropriate distribution category.

- **Low uncertainty** indicates that the available data are robust and well reviewed. It is assumed that the range on record is an accurate description for the taxon.
- **Moderate uncertainty** indicates that there is some uncertainty in the range on record or limited collection records, and that there is a reasonable probability that range may be broader or narrower than described in the available literature.
- **High uncertainty** indicates that the range on record is likely incomplete and not representative of the probable range. High uncertainty will be more likely for newly described species, or rarer species that are underrepresented in collections.

Taxa with distribution categories of 1 and 2 were generally assumed to be “No Risk” and were not subjected to further review. Further review of taxa with a value of 3 may occur where there is moderate to high uncertainty in the range on record. Any taxon with a distribution category value of 4 was flagged for further literature review, and potential independent external review. Any taxon with a distribution category value of 5 was automatically flagged for independent external review. Moderate to High uncertainty scores were applied to uncertain taxonomic designations (i.e., “cf.” taxa).

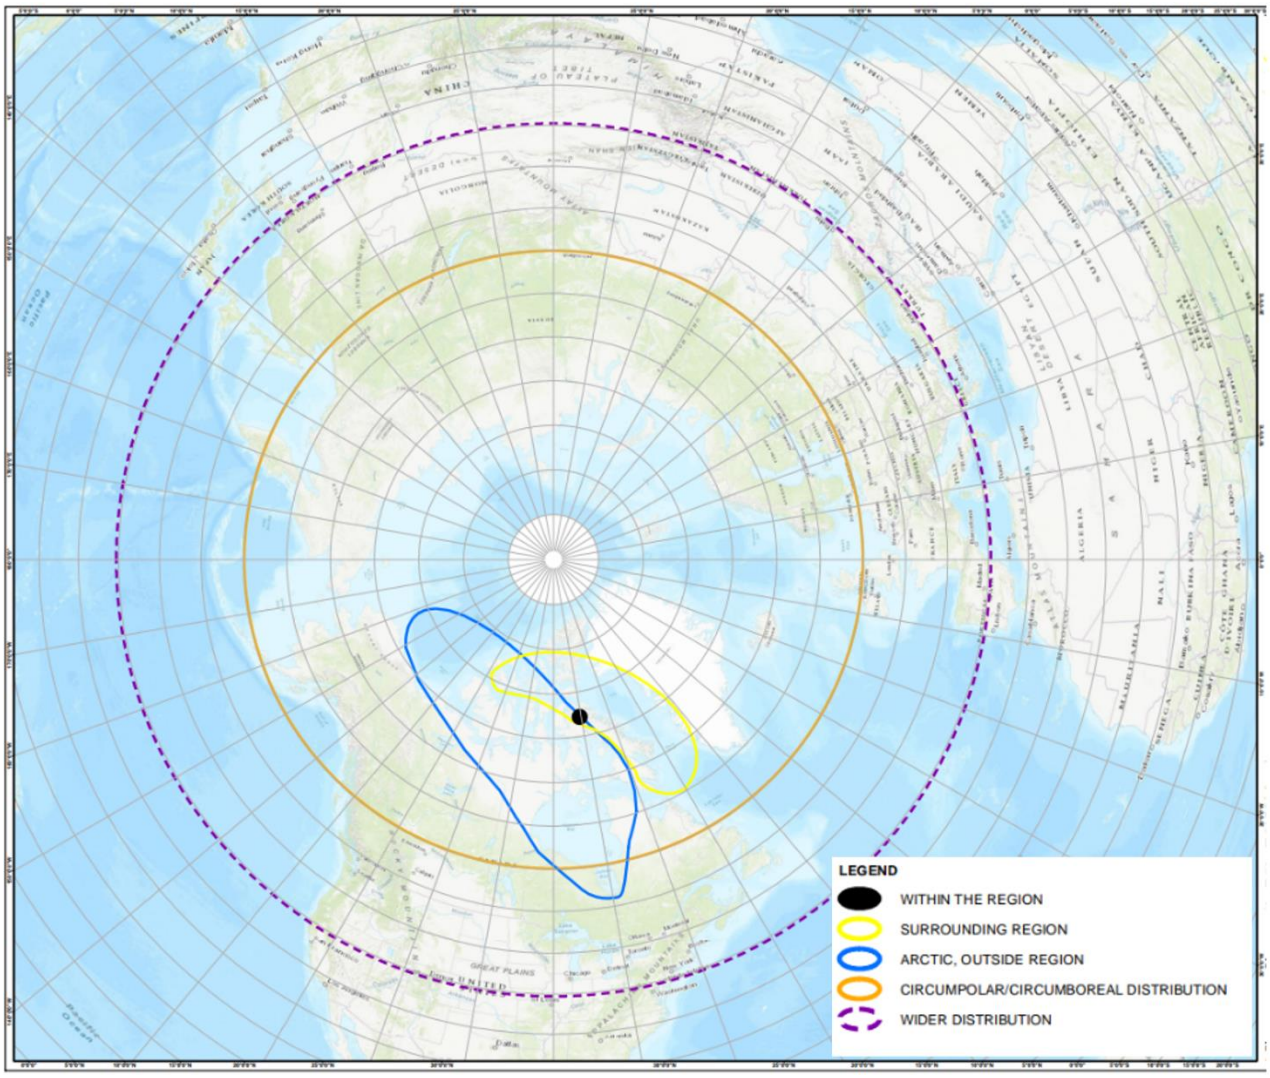

Figure 8-4: Approximate regions for taxonomic distribution categories used to define closest records. Adapted from Goldsmit et al. (2014).

8.3.3.3.2 Limitations

Specimens were not always identified to the species level due to a variety of limitations such as incomplete or disputed morphological descriptions available for some taxonomic groups, missing or undeveloped (juvenile) features, or damage to specimens. These specimens were recorded to the lowest practical taxonomic level as indet. (indeterminate) or sp. (species) when identifiable to the genus level. When an inexact match to a species was made, the designations cf. (compare with) and sp. nr. (species near) were used to indicate the specimen was similar to or represented an unknown species near to the indicated taxon, respectively (see Section 8.1.2 Definitions). For literature review, where taxa were not identifiable to the species level, the distribution or range of the higher taxon to which the specimen was identified was examined. For example, if a specimen from Milne Inlet could only be identified to genus, and the databases revealed that no species within that genus had ranges that included the Canadian Arctic, the specimen was flagged for further review.

Determining the status of some taxa was complicated by lack of data as well as poor or unreliable records. Biodiversity and species assemblages in the Canadian Arctic are not well studied, particularly in comparison to the Eurasian Arctic (Sirenko et al. 2024, Figure 8-5). Surveys and species inventories in the Canadian Arctic are not exhaustive, and species descriptions may not include a comprehensive description of range. Rarer and more recently described taxa may not have a report of occurrence or range on record within Canadian Arctic waters despite having the potential to be present. In many areas of the Canadian Arctic, much of the survey effort was undertaken in the 1970s or 1980s, and species inventories reflect the taxonomy of the time which may have changed due to subsequent taxonomic revisions, sometimes leading to uncertainty as to which species is recorded.

Species where the native range is unknown, disputed, or uncertain are considered cryptogenic, being unable to be classified as native or introduced in a given region (Carlton, 1996). The introduction status of these species is unknown either due to lack of information or disagreement among multiple lines of evidence and may represent a substantial proportion of species in an area, for example, cryptogenic species in San Francisco Bay, California, represented 37% of the total of introduced and cryptogenic species, despite over 30 years of study of NIS in the area (Carlton, 1996). In this study, a species may be considered cryptogenic to the Project area if the described range includes the Western North Atlantic and Arctic waters outside of the Eastern Canadian Arctic.

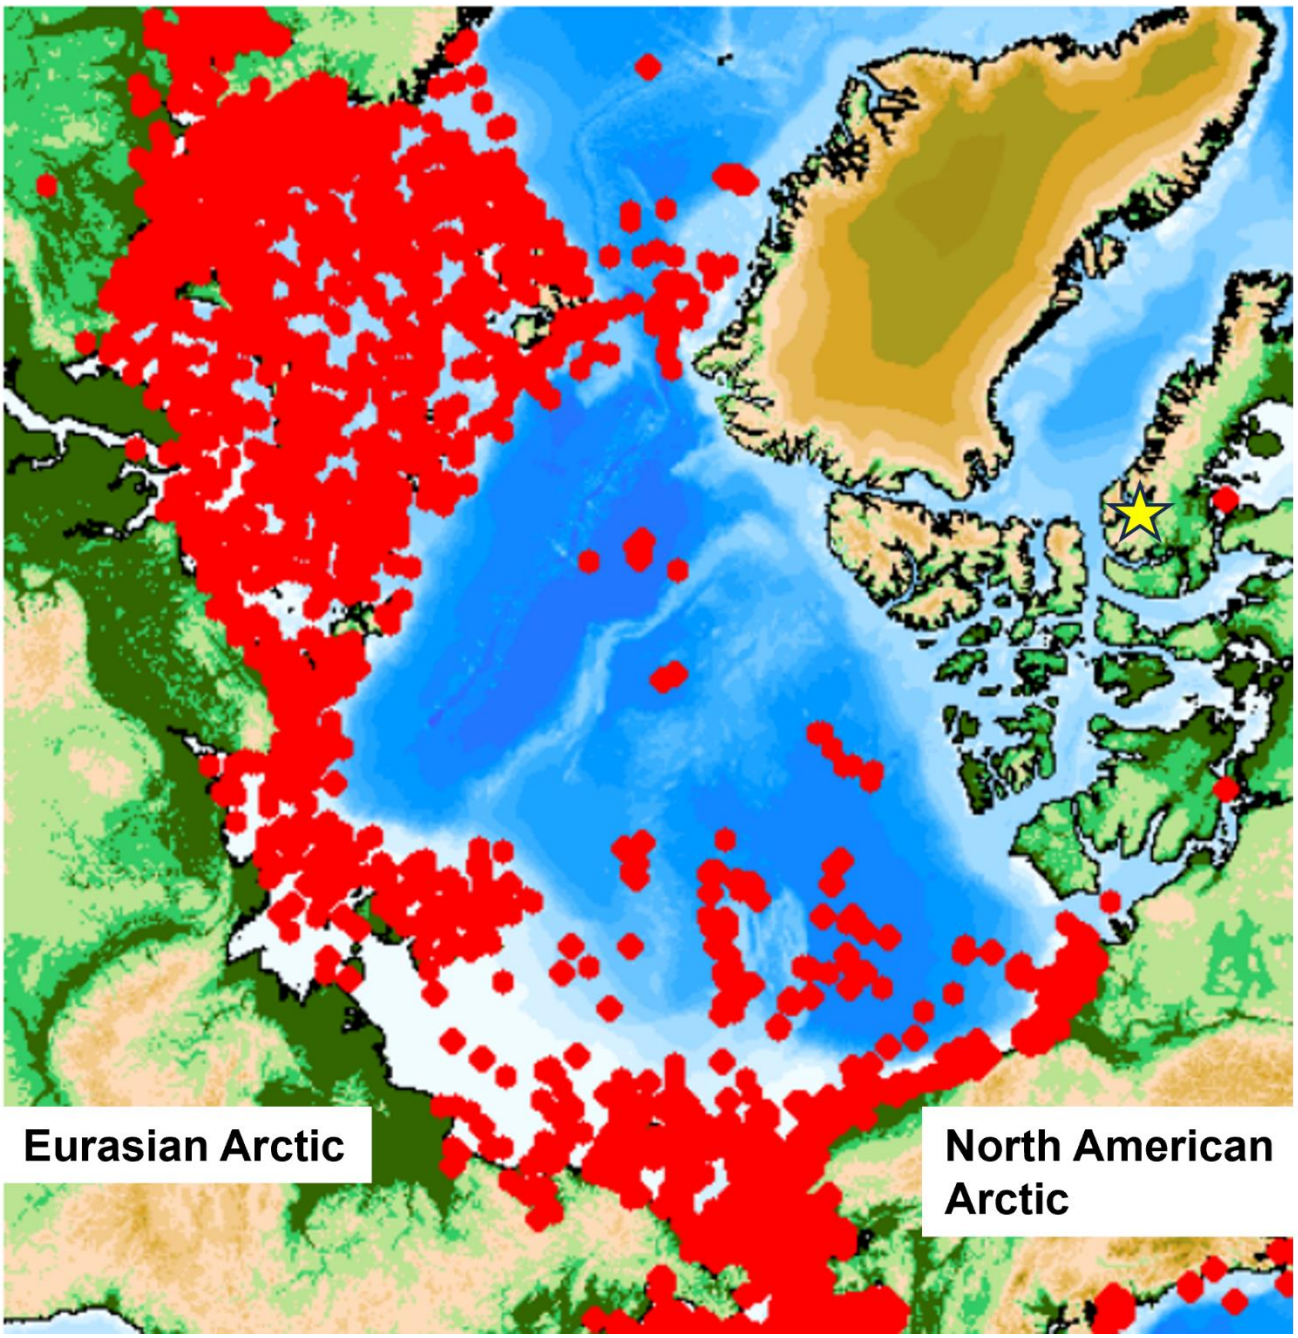

Figure 8-5: Arctic species datasets available through ArcOD (the centralized international database and species inventory of Arctic Ocean Diversity, www.arcodiv.org), one of the sources of information reviewed for species records, illustrating the discrepancy between the number of published studies in Canadian waters (right side) compared to other areas of the Arctic Ocean (left side). Image produced by ArcOD (2024). Yellow star indicates Project area.

8.3.3.4 Independent Verification of Identification

Following literature review, specimens that were flagged as requiring closer examination underwent secondary taxonomic review by Biologica and were sent for independent verification to the Benthic Ecology Lab at Université Laval (Laval). Following review by Laval, specimens were forwarded to specialists in specific taxonomic groups if further clarification was required.

Samples were sent for independent verification if they were flagged as potential non-indigenous or invasive species. Other reasons for independent verification included the existence of a new species description in the scientific literature which might affect a previous identification, limited information on the distribution, or uncertainty in the identification.

Specimens sent to specialists in 2023 were additional specimens of taxa identified during the 2022 MEEMP and NIS/AIS program that were pending verification with specialists.

8.4 Results

8.4.1 Taxonomic Identification

8.4.1.1 Benthic Infauna

Benthic infaunal sampling in 2023 was conducted at 31 stations in Milne Port, yielding a total abundance of 160,026 infaunal organisms representing 334 taxa, or 223 unique taxa (i.e., where a higher taxonomic level was not also represented by a lower taxon) (Appendix 8A-1, 8A-2). Of these, 25 taxa were considered “new records”, four of which were new species records, meaning they were not found in previous surveys in Milne Inlet; the new records are presented in Table 8-6, along with a description of the distribution on record.

All newly recorded taxa were confirmed to have ranges that included the Canadian Arctic or the North Atlantic extending past Greenland and Southern Baffin Island (at least one record in the ecoregions of interest). Ranges were considered to have a high probability of including the Project area if the limited collections on record were georeferenced to Arctic waters or were spread across a wide geographic range that could reasonably include Canadian Arctic waters. Table 8-6 describes the recorded distribution categories and relevant ecoregions for each taxa along with an uncertainty score that indicated the level of confidence in the available data describing the range on record.

Other taxa of note that were not new observations included one taxon with a revised species name. The Lumbrinerid polychaete genus *Scoletoma* has undergone recent revision, notably with the species *S. impatiens* now considered a junior synonym for *Scoletoma laurentiana* (WoRMS 2024). Species records are not fully updated to include the accepted range for specimens identified under former names resulting in the distribution range of *S. laurentiana* appearing to be Mediterranean and Atlantic (WoRMS 2024, GBIF 2024). However, *S. impatiens* is well documented in the Canadian Arctic, with collection in the Northern Labrador, Hudson Complex, West Greenland Shelf ecoregions, as well as observations in Milne Port MEEMP surveys since 2016 (WSP 2023, Miller and Nozères 2024, Gagnon and Torgersen 2021).

Additionally, four taxa from the Watch List were collected. In 2023, a single specimen of the ampharetid *Sosane wireni* was collected. *S. wireni* was first observed in 2019 and placed on the Watch List, and again in 2020. Independent review of the specimens in 2019 and 2020 confirmed the identification. *S. wireni* had been flagged initially due to uncertainties in the range on record. The accepted range description was limited to New England; however, collection records under superseded names indicated a broader range that included Arctic waters (GBIF

2024, WoRMS 2024). No specimens were collected in 2021 and 2022 despite targeted collections in the areas where the taxon was previously observed.

Specimens of the terebellid polychaete *Paramphitrite birulai* were collected in 2023. Collection records for this species indicated a broad range including the European North Atlantic, the Western North American Arctic, and the European Arctic (WoRMS 2024; GBIF 2024, Jirkov 2020), as well as indications of a cryptogenic presence in the Adriatic Sea (Costello et al. 2024, Loia et al. 2017). Independent review of specimens in 2023 by Dr. Julio Parapar, a specialist in terebellid polychaetes, concluded that while the specimen closely matched the most recent descriptions for *P. birulai*, features required for positive identification were missing (Parapar 2023). Additionally, Dr. Parapar noted features on the third segment that are not described for any of the known species in this genus, indicating further review is required to determine whether these specimens represent an undescribed species.

An unidentified *Hesperonoe* species was first observed in 2020 benthic infauna samples and placed on the Watch List at that time. Subsequently observed in 2022, this taxon was flagged due to uncertainties in its range resulting from a limited collection record. *Hesperonoe* are commensal polychaetes (scale worms), frequently associated with urchins and shrimp, which are not typically collected in benthic samples in significant numbers, resulting in a poor identification record. At least one species has been recorded in the Canadian Arctic, but records are limited to the Beaufort Sea (Chapman and Kostylev 2008). Specimens from 2020 were sent for independent review by Laval, where the specimens were identified as *Bylgides* sp., a genus known to occur in the Project area. This identification was disputed by Biologica based on features present on the specimens that should exclude the identification of *Bylgides* (Golder 2021). Specimens from 2022 were flagged for verification, however, a specialist was not identified in time for completion of the 2022 report. *Hesperonoe* was identified in samples again in 2023, and these will be sent for verification along with 2022 specimens when an expert is identified.

Additionally, four specimens of *Marenzelleria* sp. were identified in benthic samples from two stations near Phillips Creek and one of the new Capesize vessel stations. *Marenzelleria* is a spionid polychaete genus with multiple species that naturally occur in the Canadian Arctic but has representative species (i.e., *M. viridis*) invasive to other regions including the Baltic Sea (WoRMS 2024, GBIF 2024, Thomson 1982, Sikorski and Bick 2004). *Marenzelleria* sp. were first recorded in Milne Port in 2016 but were not flagged for review until the tentative identification of *M. viridis* in 2018. Due to morphological similarities between species in this genus and the tendency of specimens to be damaged during collection, identification to species can be difficult. Specimens from 2018 through 2021 were subsequently corrected to the Arctic species *M. wireni* (via genetic analysis) and likely *M. arctia* (via morphological examination) by a specialist in the taxonomic group. The 2023 specimens were not in a condition allowing them to be identified to species.

An unidentified *Crassicorophium* specimen was collected at a station near the Ore Dock on the western transect, and on a settlement plate along the Freight Dock. This genus naturally occurs in the Canadian Arctic and was first identified in baseline surveys (*C. bonellii,* as *Corophium bonellii*) at Milne Port, but was added to the Watch List following concerns from DFO of morphological similarities to *Monocorophium*. *Monocorophium* was also identified in baseline surveys at Milne Port, however (as *Corophium insidiosum;* SEM 2016). DNA analysis conducted in 2021 on tentative *C. bonellii* specimens was inconclusive to species, but samples were a genetic match to unidentified amphipods collected from Victoria Island, Nunavut, presumed to be *C. clarencense* (Golder 2022).

Table 8-6: List of Newly Recorded Benthic Infauna Taxa Identified at Milne Inlet in 2023, with Description of Distribution on Record

Phylum Class/Order	Family	Taxon	Description	Distribution References	Distribution Category[a]	Relevant Ecoregions on Record[b]	Uncertainty[c]
Annelida							
Polychaeta / Phyllodocida	Chrysopetalidae	*Dysponetus* sp.	Broadly distributed and recorded in all oceans, this genus includes at least one species with occurrence records that include the Eastern Canadian Arctic	1, 2, 3, 4, 5	2 Surrounding Region	1, 4, 5, 6, 7	Low
Polychaeta / Phyllodocida	Phyllodocidae	*Mystides borealis*	Limited collection records indicate that this species is widespread and occurs in the Eastern Canadian Arctic	1, 2, 3, 4, 5	2 Surrounding Region	4, 5	Low
Polychaeta / Phyllodocida	Sphaerodoridae	*Sphaerodoridium minutum*	Phyllodocid worm with a broad range in the northern hemisphere. Records includes various georeferenced specimens around Baffin Island	1, 2, 3, 4	2 Surrounding Region	1, 2, 4, 5, 9	Low
Polychaeta / Phyllodocida	Sphaerodoridae	*Sphaerodorum gracilis*	Phyllodocid worm with a broad range in the northern hemisphere. Records includes various georeferenced specimens around Baffin Island	1, 2, 3, 4, 5, 15	2 Surrounding Region	1, 3, 4, 5, 6, 9	Low
Polychaeta / -	Maldanidae	*Praxillura* sp.	Globally distributed genus of maldanid worms that contains representative species with ranges that include the Canadian Arctic and representative collections from Baffin Island.	1, 2, 3, 4, 5	2 Surrounding Region	1, 4, 5, 6	Low

Phylum Class/Order	Family	Taxon	Description	Distribution References	Distribution Category[a]	Relevant Ecoregions on Record[b]	Uncertainty[c]
Arthropoda							
Hexanauplia / Siphonostomatoida	-	Siphonostomatoida indet.	Order of parasitic copepods with a broad global distribution. Multiple species are known to occur in the Eastern Canadian Arctic. Some species are recorded as NIS, however they are linked with transfer of the host species, and are unlikely to be introduced through project related vectors	1, 2, 3, 6, 7	2 Surrounding Region	2, 4, 5, 6, 9	Low
Insecta / Diptera	Chironomidae	*Cladopelma* sp.	Non-biting midge species with freshwater larval stages. Genus has been recorded in the Eastern Canadian Arctic at Bylot Island	2, 8, 9	2 Surrounding Region	1, 5, 9	Low
Insecta / Diptera	Chironomidae	*Corynocera* sp.	Non-biting midge species with freshwater larval stages. Genus has been recorded in the Eastern Canadian Arctic, including unidentified species collected near Kugaaruk and Cambridge Bay	2, 8	3 Arctic, Outside Region	2, 7, 9	Low
Insecta / Diptera	Chironomidae	*Paratanytarsus* sp.	Genus of non-biting midges with a broad global distribution. Recorded in the Eastern Canadian Arctic, including Bylot Island, and documented in streams and lakes around the Mary River Mine site	2, 10, 11, 21	1 Within the Region	1, 2, 3, 4, 5, 8, 9	Low
Insecta / Diptera	Chironomidae	*Rheotanytarsus* sp.	Genus of non-biting midges with a broad global distribution. Recorded in the Eastern Canadian Arctic, and documented in streams and lakes around the Mary River Mine site	2, 10, 11, 21	1 Within the Region	1, 2, 5, 9	Low

Phylum Class/Order	Family	Taxon	Description	Distribution References	Distribution Category[a]	Relevant Ecoregions on Record[b]	Uncertainty[c]
Insecta / Diptera	Chironomidae	*Stictochironomus* sp.	Genus of non-biting midges with a broad global distribution. Recorded in the Eastern Canadian Arctic, and documented in streams and lakes around the Mary River Mine site	2, 10, 11, 12	1 Within the Region	1, 2, 5, 9	Low
Insecta / Diptera	Chironomidae	*Pseudokiefferiella* sp.	Genus of non-biting midges with a broad global distribution. Recorded in the Eastern Canadian Arctic, and documented in streams and lakes around the Mary River Mine site	2, 10, 11, 21	1 Within the Region	1, 2, 3, 4, 5, 7, 8, 9	Low
Insecta / Diptera	Chironomidae	*Heterotrissocladius* sp.	Genus of non-biting midges with a broad global distribution. Recorded in the Eastern Canadian Arctic, and documented in streams and lakes around the Mary River Mine site	2, 10, 11, 12, 21	1 Within the Region	1, 2, 3, 4, 5, 6, 8, 9	Low
Insecta / Diptera	Chironomidae	*Hydrosmittia* sp.	Genus of non-biting midges with a broad global distribution. Recorded in the Eastern Canadian Arctic, and documented in streams and lakes around the Mary River Mine site	2, 10, 21	1 Within the Region	1, 3	Low
Insecta / Diptera	Chironomidae	*Parakiefferiella* sp.	Specimen did not match any described species within the genus. Genus of non-biting midges with a broad global distribution. Recorded in the Eastern Canadian Arctic and documented in streams and lakes around the Mary River Mine site. Records in the Eastern Canadian Arctic are largely unidentified species or cf. taxon	2, 10, 11, 12, 21	1 Within the Region	1, 2, 3, 4, 5, 9	Low

Phylum Class/Order	Family	Taxon	Description	Distribution References	Distribution Category[a]	Relevant Ecoregions on Record[b]	Uncertainty[c]
Insecta / Diptera	Chironomidae	Pentaneurini indet.	Tribe of non-biting midges with a broad global distribution. Multiple genera within this tribe have been recorded in the Eastern Canadian Arctic and documented in streams and lakes around the Mary River Mine site.	2, 10, 11, 12	1 Within the Region	1, 2, 3, 4, 5, 6, 9	Low
Insecta / Diptera	Chironomidae	*Thienemannimyia* group sp.	Genus of non-biting midges with a broad global distribution. Recorded in the Eastern Canadian Arctic and documented in streams and lakes around the Mary River Mine site	2, 10, 11, 21	1 Within the Region	1, 4	Low
Insecta / Diptera	Tipulidae	*Tipula* (*Arctotipula*) sp.	An Arctic/Boreal subgenus of craneflies, with multiple species in the Canadian Arctic, including documented occurrences on Baffin Island. *Tipula* sp. are documented in streams and lakes around the Mary River Mine site.	2, 10, 11, 13	2 Surrounding Region	1, 2, 4, 5, 9	Low
Insecta / Plecoptera	Chloroperlidae	Chloroperlidae indet.	Stonefly family found primarily throughout the northern hemisphere. Recorded through the Canadian Arctic	2	3 Arctic, Outside Region	4, 5, 9	Low
Malacostraca / Amphipoda	Isaeidae	Isaeidae indet.	Records of this amphipod family in the Canadian Arctic are ambiguous due to multiple taxonomic revisions resulting in some Isaeidaen species being revised to new families. Records in the Eastern Canadian Arctic are not resolved beyond family.	1, 2, 5, 14, 15	3 Arctic, Outside Region	5	Moderate

Phylum Class/Order	Family	Taxon	Description	Distribution References	Distribution Category[a]	Relevant Ecoregions on Record[b]	Uncertainty[c]
Malacostraca / Nebaliacea	Nebaliidae	*Nebalia* sp.	Leptostracan genus with a broad range on record. This genus is well documented in the Eastern Canadian Arctic	1, 2, 3, 5, 15	2 Surrounding Region	4, 5, 6, 8, 9	Low
Chordata							
Teleostei / Perciformes	Stichaeidae	*Anisarchus medius*	Stout Eelblenny is well documented throughout the Canadian Arctic and around Baffin Island	1, 2, 3, 16, 17, 18	2 Surrounding Region	4, 5, 6, 9	Low
Echinodermata							
Asteroidea / Paxillosida	Ctenodiscidae	*Ctenodiscus crispatus*	Seastar species with a broad range throughout the northern Hemisphere. Records in the Eastern Canadian Arctic include Davis Strait, Baffin Island and Lancaster Sound	1, 2, 3, 5, 17, 19, 20	2 Surrounding Region	1, 3, 4, 5, 6	Low
Asteroidea / Valvatida	Solasteridae	Solasteridae indet.	Family of seastars with a broad global range and multiple species within the Canadian Arctic. Eastern Canadian Arctic collections include specimens from Koluktoo Bay. *Crossaster papposus* observed in quadrat surveys in 2023 (Section 8.4.1.2)	1, 2, 3, 5, 14, 17	1 Within the Region	1, 2, 3, 4, 5, 6, 7, 8, 9	Low

Phylum Class/Order	Family	Taxon	Description	Distribution References	Distribution Category[a]	Relevant Ecoregions on Record[b]	Uncertainty[c]
Mollusca							
Caudofoveata / Chaetodermatida	Chaetodermatidae	*Chaetoderma nitidulum*	An aplacophoran mollusc species that is well documented in the Canadian Arctic and has also been documented in Davis Strait in Western Greenland. Unknown species from the genus *Chaetoderma* have been observed in Milne Port benthic infaunal samples since 2015.	1, 2, 3, 19	2 Surrounding Region	6, 9	Low

Notes: Taxa identified to the lowest practical taxonomic level; *indicates non-unique taxa; indet.= indeterminate (taxa which could not be identified beyond the taxonomic level listed); sp.=species.
[a] Distribution categories indicate the proximity to the Project of the closest georeferenced collection of the taxon, where category 1: Within the Region, 2: Surrounding Region, 3: Arctic, Outside Region, 4: Circumpolar/Circumboreal Distribution, 5: Wider Distribution. Distribution categories are defined in Section 8.3.2.1.1
[b] Ecoregion are delineated in Spalding et al. 2007 and herein refer to 1. Baffin Bay-Davis Strait; 2. Lancaster Sound; 3. High Arctic Archipelago; 4. Northern Labrador; 5. Hudson Complex; 6. All taxa cross-referenced with NIS/AIS resources: Fofonoff et al. 2018, ISSG 2024, Costello et al. 2024, Molnar et al. 2008, Casas-Monroy et al. 2014.

8.4.1.2 Macroflora and Benthic Epifauna

A total of 47 distinct macroflora and epifauna taxa were recorded during quadrat surveys in Milne Inlet in 2022, 19 of which were identifiable to the species level. The complete list of identified taxa is presented along with the fish and incidental taxa in Appendix 8B-1. Of these, only one taxon (*Crossaster papposus*) was considered a new record for Milne Inlet, meaning it was not found in previous surveys in Milne Inlet; the new record is presented in Table 8-7, along with a description of the distribution on record.

No taxa from the Program Watch List were detected during permanent quadrat surveys and no taxa were flagged for review.

Table 8-7: List of Newly Recorded Taxa Identified In Quadrat Surveys at Milne Inlet in 2023, with Description of Distribution on Record

Phylum Class/Order	Family	Taxon	Description	Distribution References	Distribution Category[a]	Relevant Ecoregions on Record[b]	Uncertainty[c]
Echinodermata							
Asteroidea / Valvatida	Solasteridae	*Crossaster papposus*	Common sunstar species in the Canadian Arctic, collection records include specimens from Koluktoo Bay	1, 2, 3, 4, 5, 6, 7, 8, 9	1, 2, 3, 4, 5, 6, 7, 8, 9	1 Within Region	Low

Notes: Taxa identified to the lowest practical taxonomic level; *indicates non-unique taxa; indet.= indeterminate (taxa which could not be identified beyond the taxonomic level listed); sp.=species.
[a] Distribution categories indicate the proximity to the Project of the closest georeferenced collection of the taxon, where category 1: Within the Region, 2: Surrounding Region, 3: Arctic, Outside Region, 4: Circumpolar/Circumboreal Distribution, 5: Wider Distribution. Distribution categories are defined in Section 8.3.2.1.1

All taxa cross-referenced with NIS/AIS resources: Fofonoff et al. 2018, ISSG 2024, Costello et al. 2024, Molnar et al. 2008, Casas-Monroy et al. 2014.

8.4.1.3 Settlement Substrates

A total of 42 plates and 38 baskets were recovered following either one year of deployment or a multi-year soak period[6]. Comparable to observations in 2022, multi-year substrates appeared to have greater recruitment and percent cover between substrates collected at the same station (Appendix 8C-2), and generally had higher taxonomic richness compared to annual plates based on qualitative observations (Figure 8-6).

A total of 81 invertebrate taxa were identified on settlement substrates (Appendix 8C-1). Of these, 61 were unique records and only one taxon was considered a new record (*Eucratea loricata*), meaning it was not found in previous surveys in Milne Inlet; the new record is presented in Table 8-8, along with a description of the distribution on record. Macroalgae identifications remain pending.

Figure 8-6: Example of differences in growth on rocks from settlement baskets at station West-M (left) and settlement plates at station West-D (right) located on the Freight Dock following one-year (top) and three-year (bottom) deployment times.

[6] Multi-year deployments were three years. Due to field limitations in 2022, some annual deployments were two-year soaks.

All taxa cross-referenced with NIS/AIS resources: Fofonoff et al. 2018, ISSG 2024, Costello et al. 2024, Molnar et al. 2008, Casas-Monroy et al. 2014.

8.4.1.4 Zooplankton

Taxonomic data of zooplankton collected from 12 stations in Milne Port are presented in Appendix 8D-2. Zooplankton taxa presence/absence from baseline years to 2023 is presented below in Table 8-9, with a complete list provided in Appendix 8D-1.

A total of seventy zooplankton taxa were observed in 2023 samples, the majority of which had been detected previously in Project monitoring and were known to have natural ranges that include the Project area. The number of taxa identified in 2023 was an increase relative to all previous survey years where collections were limited to a single event.

Several taxa (Oweniidae indet., Acari indet., Clausocalinidae indet., Cyclopidae indet., *Cyclops* sp., *Hyperia* sp., Hydrozoa indet., Corymorphidae indet., Asteroidea indet., and *Clione* sp.) were observed for the first time in zooplankton samples in 2022, but these taxa, or representative lower taxonomic levels, have been observed previously in other survey methods in Milne Port. No taxa from the Program Watch List were detected and no taxa were flagged for review.

New observations included an unknown copepod species from the family Diaptomidae as well as a copepod from the genus *Monstrilla* (Table 8-10)

Table 8-9: Zooplankton Taxa Presence in Milne Inlet During NIS/AIS Monitoring in 2023 Compared to Previous Survey Years (Baseline years, 2016-2020, 2022)

Notes: Taxa in bold indicate the first observation of the taxa during MEEMP and NIS/AIS surveys. Taxa identified to the lowest practical taxonomic level; presence/absence for previous years taken from SEM 2015, 2016, 2017, Golder 2018, Golder 2019, Golder 2020, Golder 2021, WSP 2023. *=Species or taxa from lower taxonomic levels identified in other survey years and/or in other survey methods; **=Freshwater taxon; ***= Incidental (benthic or terrestrial taxa or life stages); indet.= indeterminate (taxa could not be identified beyond the taxonomic level listed); sp.=species.

(a) Baseline includes zooplankton observations in 2008, 2010, 2014, and 2015.

Table 8-10: List of Newly Recorded Zooplankton Taxa Identified at Milne Inlet in 2023, with Description of Distribution on Record

Phylum Class/Order	Family	Taxon	Description	Distribution References	Distribution Category[a]	Relevant Ecoregions on Record[b]	Uncertainty[c]
Arthropoda							
Copepoda / Calanoida	Diaptomidae	Diaptomidae indet.	Freshwater family of copepods. Limited information is available on distribution records, however multiple specimens have been collected from the Eastern Canadian Arctic as part of the International Barcode of Life Project. Representative species were documented in streams and lakes around the Mary River Mine site during baseline surveys.	2, 3, 4, 5	1, 2, 4, 5, 9	1 Within the Region	Low
Copepoda / Monstrilloida	Monstrillidae	*Monstrilla* sp.	Poorly described genus of copepods, with limited georeferenced collections and multiple taxonomic revisions. Records in the Canadian Arctic include at least two described species, in addition to multiple collections of unidentified species from the genus.	1, 2, 6, 7, 8	1, 2, 4, 5, 9	2 Surrounding Region	Moderate

Notes: Taxa identified to the lowest practical taxonomic level; *indicates non-unique taxa; indet. = indeterminate (taxa which could not be identified beyond the taxonomic level listed); sp.=species.
[a] Distribution categories indicate the proximity to the Project of the closest georeferenced collection of the taxon, where category 1: Within the Region, 2: Surrounding Region, 3: Arctic, Outside Region, 4: Circumpolar/Circumboreal Distribution, 5: Wider Distribution. Distribution categories are defined in Section 8.3.2.1.1
[b] Ecoregion are delineated in Spalding et al. 2007 and herein refer to 1. Baffin Bay-Davis Strait; 2. Lancaster Sound; 3. High Arctic Archipelago; 4. Northern Labrador; 5. Hudson Complex; 6. West Greenland Shelf; 7. North Greenland Shelf; 8. East Greenland Shelf; 9. Beaufort-Amundson-Viscount Melville-Queen Maud
[c] Uncertainty indicates confidence in the data available for the range on record. Uncertainty categories (Low, Moderate, and High) are described in Section 8.3.2.1.1
Taxa distribution references: 1: WoRMS 2024; 2: GBIF 2024; 3: Stewart 2013; 4. Chain et al. 2016; 5. NSC 2012; 6. Miller and Nozères 2024. 7. Grainger et al. 1985, 8. Buchanan and Sekerak 1982
All taxa cross-referenced with NIS/AIS resources: Fofonoff et al. 2018, ISSG 2024, Costello et al. 2024, Molnar et al. 2008, Casas-Monroy et al. 2014.

8.4.1.5 Fish and Incidentals

Throughout fish surveys at Milne Inlet, some species were targeted and caught intentionally (such as fish sampled for fish community and fish health monitoring; reported in Chapters 6.0 and 7.0) while other species were collected or observed incidentally. In 2023 MEEMP surveys, 41 taxa were collected, captured, or observed incidentally and of these, three taxa were newly recorded in MEEMP surveys (Table 8-11). The full list of incidental taxa (also including macroflora and epifauna described in Section 8.4.1.2) is available in Appendix 8B-1; laboratory results are in Appendices 8B-2 and 8B-3.

All taxa observed or caught incidentally in MEEMP and NIS/AIS surveys were screened against a global database of marine invasive species and none of the taxa were identified as a globally-recognized invasive species (Molnar et al. 2008) or an invasive species in Canada according to the National Risk Assessment for Introduction of Aquatic Nonindigenous Species to Canada by Ballast Water (Casas-Monroy et al. 2014). In addition to these databases, each taxon was researched independently in the literature for their known habitats and distributions to detect taxa that may be considered non-native to the Arctic region. For taxa that were not identified to the species level, it was confirmed that the identified higher-level taxa had at least one representative species with a distribution that included Arctic waters.

Table 8-11: Newly Recorded Incidental Taxa Identified in Milne Inlet in 2023

Phylum Class/Order	Family	Taxa	Capture Method	Description	Distribution References	Distribution Category[a]	Relevant Ecoregions on Record[b]	Uncertainty[c]
Arthropoda								
Malacostraca / Amphipoda	Pleustidae	Pleustidae indet.	Fish Stomach Contents	Amphipod family with multiple representative species in the Eastern Canadian Arctic. Two species within the family are recorded NIS to the Pacific Northwest and to the North Sea. No impacts have been reported.	1, 2, 3, 4, 5, 6	2, 3, 4, 5, 6, 8, 9	2 Surrounding Region	Low
Echinodermata								
Asteroidea / Forcipulatida	Asteriidae	*Leptasterias (Hexasterias) polaris*	Incidentals (Trawl)	North American temperate and polar species of six-armed stars. Collection records included specimens from Koluktoo Bay	1, 2, 4, 5, 7	1, 2, 3, 4, 5, 6, 9	1 Within Region	Low
Asteroidea / Paxillosida	Benthopectinidae	*Pontaster tenuispinus*	Incidentals (Trawl)	North American temperate and polar species of seastars. Collection records included specimens from Baffin Bay and Davis Strait	1, 2, 4, 7, 8	1, 2, 3, 4, 9	2 Surrounding Region	Low

Notes: Taxa identified to the lowest practical taxonomic level; *indicates non-unique taxa; indet.= indeterminate (taxa which could not be identified beyond the taxonomic level listed); sp.=species.
[a] Distribution categories indicate the proximity to the Project of the closest georeferenced collection of the taxon, where category 1: Within the Region, 2: Surrounding Region, 3: Arctic, Outside Region, 4: Circumpolar/Circumboreal Distribution, 5: Wider Distribution. [c] Uncertainty indicates confidence in the data available for the range on record. Uncertainty categories (Low, Moderate, and High) are described in Section 8.3.2.1.1
Taxa distribution references: 1: WoRMS 2024; 2: GBIF 2024; 3: OBIS 2011; 4. DFO 2019; 5. Cusson 2018; 6. Hopcroft 2019; 7. Miller and Nozères 2024, 8. Roy et al. 2015.
All taxa cross-referenced with NIS/AIS resources: Fofonoff et al. 2018, ISSG 2024, Costello et al. 2024, Molnar et al. 2008, Casas-Monroy et al. 2014.

8.4.2 Genetic Identification

Samples collected for DNA analysis are in the process of being sorted by Biologica for taxa of interest. Taxa of interest include general fouling, attached, and encrusting taxa such as macroalgae, bryozoans and tunicates where morphological identification may be generally challenging, in addition to Watch List taxa (Appendix 8E-3). The results of DNA analysis remain pending. This report will be updated as results become available. Updated taxonomic information will be presented in revisions to the 2024 monitoring report and, in the event that a potential NIS/AIS taxon is found in the pending data before the publication of the 2024 report, it will be presented to MEWG.

8.4.3 Independent Verification and Identifications

No newly identified taxa in 2023 surveys were flagged for further review due to concerns about NIS/AIS status or range on record. Several taxa from the Watch List were identified again in benthic and settlement substrate samples (*Marenzelleria* sp., *Sosane wireni*, *Crassicorophium* sp. and *Paramphitrite birulai*). These taxa had all previously been sent for independent review and the new specimens were either damaged or immature, lacking morphological features that would allow for further resolution by these experts. However, literature reviews for these taxa were updated for 2023, and where new information was available this was used to review their Watch List status.

Updates to specimens sent for verification from 2022 surveys were provided where there was new information available since submission of the 2022 report. A reviewer for *Hesperonoe* could not be identified for these specimens. The specimens were held to be sent with additional specimens from 2023 samples, should a reviewer be determined. A bryophyte specimen was sent to Dr. Terry MacIntosh, a consulting bryophyte expert with the UBC Herbarium, Beaty Biodiversity Museum in 2023; results of the independent review remain pending. An unidentified species from the bryozoan superfamily Buguloidea specimen flagged for review in 2023 was not sent for review because it was determined that the specimen was in too poor of a condition to resolve further.

Macroalgae specimens from previous years will be sent to Dr. Gary Saunders at the University of New Brunswick (UNB) along with those collected in 2023.

8.5 Discussion

8.5.1 Limitations

It is not always possible to identify specimens to the species level due to a variety of limitations. Species descriptions are often based on adult stages, and immature specimens may lack the features present in the adult that are required for specific identification (Steinerstauch 2019, pers. comm.). Fragmented samples, or samples damaged during collection, may also be missing identifying features that would be used to determine species. Incomplete species records and descriptions also lead to limitations in species identification (Steinerstauch 2019, pers. comm.).

The level of resolution possible for identifications may be dependent also on the number of individual specimens of the same type that are collected. This is for two general reasons: first, higher incidence of a type of specimen often translates to a higher incidence of specimens with diagnostic characters, and thus improved identification resolution; and second, the increase in incidence of identifiable taxa allows for more distinctions to be made about like and unlike taxa. For example, with bryozoans, a single incidence of a small colony or fragment observed in a sample is less likely to be identified to genus than it would be in a sample with a high incidence, in which opportunities to compare and contrast morphologies are greater (Macdonald 2022a, pers. comm.).

Ranges on record are not complete for all taxa. In particular, recently described or uncommon taxa may have a limited range description based on a few sites where specimens have been found, with a broader range inferred based on biological characteristics and tolerances. Additionally, with some taxa it can be difficult to determine if a species is originally from the area in which it is found, or if it was introduced from another location. In cases where the original native range cannot be conclusively determined, a species is considered cryptogenic.

Flora and fauna of the Canadian Arctic are not thoroughly described, and surveys of species in the Canadian Arctic are severely lacking relative to surveys in other Arctic and sub-Arctic regions, particularly in comparison to surveys in Northern Europe. Figure 8-5 shows the large gap in the Canadian Arctic where few datasets are represented in ArcOD, the international Arctic Ocean biodiversity database. Even for megabenthos, arguably one of the better sampled components of Arctic Canadian marine biota, 42% of the taxa in Baffin Bay and 59% in the Eastern Archipelago are estimated to remain undocumented, while even the Beaufort Sea (relatively well-studied (by Canadian Arctic comparisons) is estimated to have 34% of its benthic megafaunal taxa undocumented (Roy et al., 2015). Surveys in the Canadian Arctic are also frequently limited by methodology, focusing on methods such as benthic grabs and zooplankton tows that exclude larger hard substrates. Encrusting or fouling taxa such as bryozoans and some tunicate species may be underrepresented in the datasets due to these methodological biases. These limitations in Arctic sampling lower the confidence in the ranges on record, particularly for less common or recently described species that may be cryptogenic to a broader area, but due to their rarity and the relative survey effort, have not yet been described outside the range on record.

Difficulties in determining the historic range of a species may also be related to changes or inconsistencies in species descriptions. The range on record may be linked to a previous name or description and databases are not always updated as new descriptions are accepted. Alternatively, multiple conflicting descriptions or names for the same taxa may further confound records. New species descriptions occur when an update to the taxonomic record is accepted. This may be due to a variety of reasons including acceptance of a more senior description, DNA analysis combining (two species merging under one species name) or separating species descriptions (one species being divided into two distinct species or subspecies), or reclassification due to the identification of features that match a different taxonomic group (such as reclassification to a different genus). These limitations

may be more pronounced in certain taxonomic groups such as bryozoans and marine algae (i.e., macroflora) where there are fewer experts focused on refining the taxonomy or more variation in reporting relative to other more well-defined groups.

Identification of species by genetic means is often suggested as an alternative to traditional taxonomic methods but requires reliable, accurate reference sequences in an accessible database. Currently, there are some barriers slowing the process of populating reference databases such as the Barcode of Life Database (BOLD). First, obtaining quality DNA sequences reliably can be difficult. Macroalgae, for example, are a diverse taxonomic group, and many taxa require specialized extraction protocols and primer design. The second barrier to progress is that once the sequences are obtained, the rigour of the original identification for reference specimens must be considered, as can often be misleading due to the limitations of morphological identifications, as discussed earlier. Therefore, improvement is an iterative process, with understanding of molecular and morphological diversity developing hand in hand (MacDonald 2022a, pers. comm.).

Availability of publications may further impact descriptions, more recently published works may not be readily available or accepted by the larger taxonomic community, and updates may not be reflected in the identification keys used by the taxonomic labs.

8.5.2 Taxonomic Identification

8.5.2.1 Benthic Infauna

A total of 352 taxa were identified in benthic samples in Milne Inlet, including 25 taxa that had not previously been recorded in the Project area, six of which were new species records for the Project. An analysis of the available literature indicated each of the new records had a clearly described range and collection records that included Arctic waters. Results for the taxa sent for independent verification are discussed in Section 8.5.3.

The following were the 25 newly recorded taxa:

- An annelid worm from the genus *Dysponetus* was identified at a single station on the eastern transect. Species from this genus are recorded in all oceans, and at least one species has been collected in the Eastern Canadian Arctic (WoRMS 2024; GBIF 2024; Miller and Nozères 2024; Gagnon and Torgersen 2021; Cusson 2018).
  - ***Dysponetus* sp. is not considered to be a taxon of concern for Milne Port**
- Based on limited collection records, *Mystides borealis* is a broadly distributed species of phyllodocid worm ranging from the Antarctic to the Arctic. Records include multiple specimens from the Canadian Arctic, including Iqaluit, Hudson Strait, and Tuktoyaktuk (WoRMS 2024; GBIF 2024; Miller and Nozères 2024; Gagnon and Torgersen 2021; Cusson 2018).
  - ***Mystides borealis* is not considered to be a taxon of concern for Milne Port**
- *Sphaerodoridium minutum* is a phyllodocid worm with a broad range throughout the northern hemisphere. Records include multiple collections around Baffin Island (WoRMS 2024; GBIF 2024; Miller and Nozères 2024; Gagnon and Torgersen 2021).
  - ***Sphaerodoridium minutum* is not considered to be a taxon of concern for Milne Port**

- *Sphaerodorum gracilis* is a phyllodocid worm with a broad range throughout the northern hemisphere. Records include multiple collections around Baffin Island (WoRMS 2024; GBIF 2024; Miller and Nozères 2024; Gagnon and Torgersen 2021, Goldsmit 2016).
  - ***Sphaerodorum gracilis* is not considered to be a taxon of concern for Milne Port**
- *Praxillura* is a broadly distributed genus of maldanid worms with representative species in the Eastern Canadian Arctic (WoRMS 2024; GBIF 2024; Miller and Nozères 2024; Gagnon and Torgersen 2021; Cusson 2018).
  - ***Praxillura* sp. is not considered to be a taxon of concern for Milne Port**
- Siphonostomatoida is an order of parasitic copepods with representative species in the Canadian Arctic, including species from the genera *Coregonicola* and *Salmonicola*, which are parasitic to fish (WoRMS 2024; GBIF 2024; Stewart and Bernier 1999). Records in the Eastern Canadian Arctic include *Artotrogus orbicularis* and *Choniostoma paradoxum*, whose hosts species are not recorded (OBIS 2024, GBIF 2024). Multiple species in this order are recorded as NIS, however due to a relative lack of free-swimming behaviour, invasion risk is largely linked to introduction of the host fish species (Costello et al. 2024, NSC 2006), which is unlikely to occur through Project-related vectors. Notably, *Salmincola lotae* which is considered to be a Eurasian species is a parasite which is recorded as a potential invader to the Canadian Arctic (NSC 2006), where its host species burbot (*Lota lota*), is already naturally present. However, there are indications that this species' native range may include Canadian waters (Stewart and Bernier 1999; Kipp et al. 2024).
  - **Siphonostomatoida indet. is not considered to be a taxon of concern for Milne Port**
- Benthic infaunal samples contained multiple specimens of freshwater associated insect taxa. While these taxa represented new observations in marine surveys, *Paratanytarsus* sp., *Rheotanytarsus* sp., *Stictochironomus* sp., *Pseudokiefferiella* sp., *Heterotrissocladius* sp., *Parakiefferiella* sp., Pentaneurini indet., and *Thienemannimyia* sp. were all identified in baseline surveys of freshwater aquatic habitat associated with the Mary River Mine site and are not considered new observations for the Project (NSC 2012).
  - ***Paratanytarsus* sp., *Rheotanytarsus* sp., *Stictochironomus* sp., *Pseudokiefferiella* sp., *Heterotrissocladius* sp., *Parakiefferiella* sp., *Pentaneurini* sp., and *Thienemannimyia* sp. are not considered taxa of concern for Milne Port**
- *Cladopelma* is a genus of non-biting midges with species that occur in the Canadian Arctic (GBIF 2024, ISU 2024. Records include an unidentified species collected at Bylot Island (GBIF 2024).
  - ***Cladopelma* sp. is not considered a taxon of concern for Milne Port.**
- *Corynocera* is a poorly described genus of midges with limited collection records. However, records do include unidentified species from this genus in the Canadian Arctic in the Lancaster Sound ecoregion, as well as fossil specimens from Eastern Greenland (GBIF 2024). Biologica indicated that the specimen collected at Milne Port might be *C. oliveri*, however the specimen was lacking features to make a positive identification. *C. oliveri* is associated with northern and cold-water lakes (Wilson and Gajewski 2004, Barley et al. 2006, Fortin and Gajewski 2011). Records indicate that this species, or a morphologically similar species (referred to as *Corynocera oliveri* type) occurs in northern Canada (north of 60 degrees latitude) and is known to occur on Baffin Island (Nishikawa 2022, Barley et al. 2006).

- **_Corynocera_ sp. is not considered a taxon of concern for Milne Port.**

- *Hydrosmittia* is a genus of non-biting midges with a broad global distribution inferred from a limited collection record. Studies of Eastern Canadian Arctic chironomids indicate that at least four species occur on Baffin Island and the high Arctic Archipelago (Namayandeh et al. 2016).
  - **_Hydrosmittia_ sp. is not considered a taxon of concern for Milne Port.**
- At least one species from the subgenus *Tipula* (*Arctotipula*) is confirmed to occur on Baffin Island (Brodo et al. 2022). *Tipula* was confirmed to occur in the Project area during freshwater aquatic habitat baseline surveys, however, these surveys did not resolve identification for most taxa beyond the genus level. It is uncertain whether the *Tipula* sp. observed would be considered from the same subgenus.
  - **_Tipula_ (_Arctotipula_) sp. is not considered to be a taxon of concern for Milne Port**
- Stoneflies, including green stoneflies (family Chloroperlidae) are generally described as restricted to lower latitudes in the Arctic. Within the Canadian Arctic, Chloroperlidae has not been recorded off the mainland (GBIF 2024). Plecopterans (stoneflies) in general are considered rare off the mainland, with studies of EPT (Ephemeroptera, Plecoptera, and Trichoptera) diversity finding a complete lack of Plecoptera in freshwater locations on Baffin Island (e.g., Namayandeh and Quinlan 2011). However freshwater baseline studies indicate that Plecopterans are present in lakes and streams around the Mary River mine site in very low abundances. These findings indicate it is possible that the range for Chloroperliidae may similarly extend further north and include rare occurrences around the Project area.
  - **Chloroperlidae indet. is not considered a taxon of concern for Milne Port**
- The amphipod family Isaeidae has undergone multiple revisions and currently contains two accepted genera with very limited descriptions. Due to the revisions, occurrence records for this family are uncertain. For example, Cusson (2018) reports *Eurystheus melanops* in the Canadian Arctic, however, this species is now accepted as *Gammaropsis melanops,* which is in the family Photidae. Stewart (2013) describes *Protomedeia fasciata* as present in the Tarium Niryutait Marine Protected Area, but this species is from the family Corophiidae. Other records in the Canadian Arctic are limited to unidentified Isaeidaens and it is uncertain if those records would also be revised (Goldsmit 2016, GBIF 2024, OBIS 2024).
  - **Isaeidae indet. is not considered a taxon of concern for Milne Port.**
- *Nebalia* is a Leptostracan genus with a broad global range. While Biologica was unable to make a conclusive identification, the specimen had features that indicated it was potentially *N. bipes*, a species with a distribution record that includes the Eastern Canadian Arctic. NEMESIS lists *Nebalia* sp. A as under review, with no indications of the location for potential introduction or rationale for why the taxon is under review (Foffonof et al. 2018).
  - **_Nebalia_ sp. is not considered a taxon of concern for Milne Port.**
- The Stout Eelblenny (*Anisarchus medius*) is a northern fish species with a robust record throughout the Arctic (WoRMS 2024; GBIF 2024). In the Canadian Arctic, Stout Eelblenny is particularly common around southern Baffin Island (Coad and Reist 2008).
  - **_Anisarchus medius_ is not considered a taxon of concern for Milne Port.**

- *Ctenodiscus crispatus*, the common mudstar, is a prolific sea star species with a broad global range (WoRMS 2024; GBIF 2024). Eastern Canadian Arctic records included multiple specimens collected throughout Davis Strait, Baffin Bay, and Lancaster Sound.
  - ***Ctenodiscus crispatus* is not considered a taxon of concern for Milne Port.**
- Solasteridae is a seastar family with a broad global range that includes multiple species within the Canadian Arctic. Eastern Canadian Arctic collections include *Solaster papposus* (now accepted as *Crossaster papposus*) collected in Koluktoo Bay. *Crossaster papposus* was also observed for the first time in MEEMP surveys in quadrat surveys in 2023 (see Section 8.4.1.2).
  - **Solasteridae indet. is not considered a taxon of concern for Milne Port.**
- *Chaetoderma nitidulum* is an Aplacophoran (shell-less molluscs) species with a broad range that includes the Canadian Arctic Unidentified specimens from the genus *Chaetoderma* have been observed in benthic surveys since 2015 (WSP 2023).
  - ***Chaetoderma nitidulum* is not considered a taxon of concern for Milne Port.**

8.5.2.2 Macroflora and Benthic Epifauna

Dive surveys of the permanent quadrats, performed to assess for presence of macroflora and epifauna species, included collection of algae and invertebrate specimens for taxonomic assessment. Among the 48 distinct macroflora and epifauna taxa recorded during quadrat surveys in Milne Inlet in 2023, there was the following new species observation:

- The rose star or common sunstar, *Crossaster papposus* is broadly distributed and common throughout the Canadian Arctic. Eastern Canadian Arctic collections include specimens collected in Koluktoo Bay under its former name *Solaster papposus* (Miller and Nozères 2024).
  - ***Crossaster papposus* is not considered a taxon of concern for Milne Port.**

8.5.2.3 Settlement Substrates

Previous experience with settlement substrates in Milne Port indicated that deployment duration is a large factor in the ability to detect organisms (WSP 2023). In most years, a single year of deployment has not resulted in many successful identifications of organisms using visual taxonomic methods. The program was adjusted in 2020 to focus on longer term deployments, with plates and baskets soaking for three years prior to recovery. Plates and baskets collected in 2023 represent the first year of the planned three-year soak time for the adjusted program. Additional plates and baskets have been collected annually to aid in early detection of recruitment of NIS/AIS in Milne Port. Due to limitations in previous years, including loss of deployments or logistical constraints, some annual substrates were collected following a two-year deployment (see Table 8-1 for details).

Overall, the fouling community observed on multi-year substrates demonstrated greater recruitment, percent cover, and taxonomic richness compared to annual substrates. Additionally, invertebrates on multi-year substrates were more likely to be at later developmental stages, facilitating identification. A higher proportion of taxa on multi-year substrates were able to be identified to species level compared to those on annual

deployments (31.1% compared to 26.6%). A total of 81 animal taxa were identified on settlement substrates, one of which was a new observation in Milne Port surveys. An analysis of the available literature indicated the following new record had a clearly described range and collection records that included Arctic waters:

- Two colonies of the bryozoan species *Eucratea loricata* were found on settlement substrates deployed at two stations along the Freight Dock. *E. loricata* has a broad range throughout the northern hemisphere. Collection records indicate that the species has a well-established circumpolar presence, including georeferenced specimens collected from the Eastern Canadian Arctic, including Baffin Island (WoRMS 2024, GBIF 2024, Roy et al. 2015). The genus *Eucratea* was observed previously in MEEMP surveys in 2020 and 2022 (Golder 2021; WSP 2023)
    - ***Eucratea loricata* is not considered a taxon of concern for Milne Port**

Macroalgae identifications based on morphological and genetic assessment are pending and will be updated as results become available. Updated taxonomic information will be presented in revisions to the 2024 report and, in the event that a potential NIS/AIS taxon is detected, it will be presented to MEWG.

8.5.2.4 Zooplankton

A total of 70 zooplankton taxa were observed in 2023 samples. The majority of taxa had been observed in previous surveys in Milne Port and were known to have natural ranges that include the Project area. No taxa from the Program Watch List were detected and no taxa were flagged for review.

The following were new records:

- Diaptomidae is a family of freshwater copepods with limited collection records in the Canadian Arctic, however these records indicate there are multiple species present (GBIF 2024). At least one diaptomid species (*Diaptomus minutus*) was observed in freshwater baseline surveys in multiple lakes and streams around the Mary River Mine site (NSC 2012).
    - **Diaptomidae indet. is not considered a taxon of concern for Milne Port**
- The copepod genus *Monstrilla* has undergone many taxonomic revisions and many species within this genus are poorly described and have no described range on record (WoRMS 2024, Suárez-Morales and Grygier 2021). At least two species (*M. longa* and *M. nasuta*) have been recorded in the Eastern Canadian Arctic (GBIF (2024). AquaNIS lists three species (*M. grandis, M. helgolandica* and *M. longicornis*) from this genus as NIS taxa (CRPI 2024), although one species (*M. helgolandica*) is no longer accepted as a *Monstrilla* species. These records of NIS *Monstrilla* may be cryptogenic morphologically related species or incorrectly inferred from limited collection data, as discussed by Suárez-Morales and Grygier (2021).
    - ***Monstrilla* sp. is not considered a taxon of concern for Milne Port**

Survey efforts in 2023 were expanded to cover a broader range of the open water season, in an effort to more accurately represent the variability of zooplankton populations throughout the season. Rather than a single collection at each station, three collections were made at each station between late July and early September. This resulted in an increase in the number of zooplankton taxa identified in 2023 relative to all previous survey years. Additionally, close to 33% of all observed taxa were observed in only one of the three survey events, highlighting the variance in zooplankton populations over time. It is recommended that this expanded survey be repeated in future years to better characterise the zooplankton populations in Milne Port.

8.5.2.5 Fish and Incidentals

All taxa observed during marine surveys at Milne Port are considered under the NIS/AIS program. This includes fish captures, non-targeted captures during fishing efforts, as well as taxa found in stomach contents. Of the 41 taxa collected, captured, or observed incidentally, three taxa were newly recorded in MEEMP surveys (i.e., not previously reported in the Milne Inlet Taxonomic Inventory).

All taxa observed incidentally in MEEMP and NIS/AIS surveys were cross-checked against marine invasive species databases. None of the taxa observed were identified as globally recognized invasive species (Molnar et al. 2008) or as domestically recognized invasive species according to the National Risk Assessment for Introduction of Aquatic Nonindigenous Species to Canada by Ballast Water (Casas-Monroy et al. 2014). In addition to these databases, the distribution and habitat preferences of each taxon was researched independently in the literature for signs of NIS status in the Arctic region. For specimens that could not be resolved to species, review efforts focused on confirming that the higher-level classification (e.g., genus) had at least one species with a distribution that included Arctic waters.

The following were new records:

- *Leptasterias* (*Hexasterias*) *polaris*, the polar six-rayed star, was observed as an incidental capture during trawl surveys. *L. polaris* is a North American temperate and Arctic seastar with a well-documented presence in the Eastern Canadian Arctic (WoRMS 2024; GBIF 2024). Eastern Canadian Arctic records included multiple specimens collected throughout Davis Strait, Baffin Bay, the high Arctic Archipelago, and Lancaster Sound, as well as collections from Koluktoo Bay (Miller and Nozères 2024).
    - ***Leptasterias* (*Hexasterias*) polaris is not considered a taxon of concern for Milne Port.**
- *Pontaster tenuispinus*, is a polar seastar often found in deeper waters and as by-catch in benthic trawls. *P. tenuispinus* has been recorded throughout the Canadian Arctic, including within Baffin Bay, Davis Strait, and Lancaster Sound (WoRMS 2024; GBIF 2024).
    - ***Pontaster tenuispinus* is not considered a taxon of concern for Milne Port.**
- An unidentified amphipod from the family Pleustidae was observed in stomach contents from two fourhorn sculpin specimens captured in the Koluktoo Bay reference area. An unidentified amphipod found in settlement substrates was also tentatively identified as from this family. Multiple representative species from this family have been recorded in the Eastern Canadian Arctic (WoRMS 2024; GBIF 2024). Two species, *Incisocalliope derzhavini* and *I. aestuarius*, have been reported as NIS to Pacific North America and the North Sea, respectively. The invasive status of *I. derzhavini* is questionable, as museum collections indicate that the species was present in San Francisco Bay almost 40 years prior to the species first description in Japan and 65 years prior to it being first observed and considered introduced to North America (Carlton and Schwindt 2024, Fofonoff et al. 2018). *I. aestuarius* has a poorly described native range along the North American Atlantic coast inferred from 15 specimens (GBIF 2024).
    - **Pleustidae indet. is not considered a taxon of concern for Milne Port.**

8.5.3 Genetic Identification

Results of genetic identification remain pending.

8.5.4 Independent Verifications and Program Watch List

Results of independent verification through morphological assessment are pending and will be updated as reviews become available. Updated results will be presented in revisions to the 2023 report and, in the event that updated information alters the NIS/AIS status of a taxon found at Milne Port such that it could be added or removed from the Watch List or Trigger List, will be presented to MEWG. The NIS/AIS program is conducted at a surveillance level and designed to flag potential invasive or non-indigenous species; the independent verification process is a crucial element of the program, ensuring third party review by global specialists in particular taxa. A summary of specimens flagged for review is provided in Table 8-13 and results of verifications will be updated as they become available. A summary of all newly recorded taxa in 2023 and their risk statuses is presented in Appendix 8E-1 and the record of verifications is available in Appendix 8E-2. A complete list of the Project Watch List for Milne Port is included in Appendix 8E-3.

Table 8-13: Summary of External Taxa Verifications (2022 and 2023)

Initial ID	Year(s) Present	Verification Method	Independent ID (Reviewer)	Risk[1]	Action	Rationale
Annelida						
Hesperonoe sp.	2020, 2022, 2023	Morphological assessment	TBD	Low Risk	Watch List	Unidentified species from the genus *Hesperonoe* were flagged in 2020 due to *Hesperonoe* being a poorly described genus with limited georeferenced collection records. Specimens were collected again in 2022 and sent for independent review. Currently the identification is considered unresolved and the taxon remains on the Watch List as Low Risk.
Bryophyta						
Bryophyta indet.	2022	Morphological assessment	TBD	No Risk	None	Global phylum of mosses, collection records include specimens from the Eastern Canadian Arctic, including Baffin Island in close proximity to Milne Port and at Ragged Island. Sent for independent review with a specialist at University of British Columbia to further resolve the identification.
Ochrophyta						
cf. *Punctaria latifolia*	2022	Morphological assessment	TBD (UNB)	Low Risk	Watch List	Specimen was an inexact match to *Punctaria latifolia*, a filamentous brown alga that has no records of occurrence in the Canadian Arctic. Listed on an AIS database as cryptogenic in Australia. Currently the identification is considered unresolved, and the taxon has been precautionarily placed on the Watch List as Low Risk.
cf. *Stictyosiphon soriferus*	2022	Morphological assessment	TBD (UNB)	Low Risk	Watch List	Specimen was an inexact match to *Stictyosiphon soriferus*, a brown alga that has a single record of occurrence in the Canadian Sub-Arctic (Churchill). Listed on an AIS database as Introduced in Australia. Currently the identification is considered unresolved, and the taxon has been precautionarily placed on the Watch List as Low Risk.

[1] Risk category refers to the taxonomic description following independent verification.

8.5.4.1 Sosane wireni

The ampharetid polychaete *Sosane wireni* was first observed in 2019 and again in 2020. Independent review of the specimens in 2019 and 2020 confirmed the identification although the identification was left as *Sosane* sp. nr. *wireni*, indicating an uncertain match (Golder 2020). The accepted range description was limited to New England; however, collection records under superseded names indicated a broader range that included Arctic waters (GBIF 2024, WoRMS 2024), as well as collections from Western Greenland (Sejr 2009). Laval University confirmed the identification of *S. wireni* in 2020 *Sosane* sp. nr. *wireni* was placed on the Watch List for further monitoring due to the range uncertainties, although it was not considered a taxon of concern (Golder 2021). No specimens were collected in 2021 and 2022 despite targeted collections in the areas where it was previously observed.

Based on the broad Atlantic and Arctic distribution, in particular the collections from Western Greenland, it is considered unlikely that these specimens represent an introduction in Canadian Arctic waters. *Sosane wireni* is designated No Risk and will be removed from the program Watch List.

- ***Sosane wireni* is designated as No Risk and is not considered a species of concern in Milne Inlet.**

8.5.4.2 Paramphitrite birulai

The terebellid polychaete *Paramphitrite birulai* is poorly described with a limited taxonomic record. No range description exists for this species, but collection records indicate the range may be wide and include the European North Atlantic and high Arctic oceans (WoRMS 2024; Jirkov 2020). There are also potential indications of introductions in the Adriatic Sea, where it is described as non-indigenous, but not invasive (Costello et al. 2024, Loia 2017). Uncertainty in the range of this taxa is compounded by disagreement in the accepted name, with some sources indicating the species is *Amphitrite birulai*, which has a narrower range on record, with type localities in Scandinavian waters (WoRMS 2024). Collection records in North America are limited to a single specimen collected off the coast of Labrador in 1987 (Gagnon and Torgersen 2021) and in Yukon/Alaska under the junior synonym *P. tetrabranchiata* (GBIF 2024). There are also indications that the taxonomic record for *Paramphitrite* species is incomplete and requires further review (LaVesque et al. 2021).

The specimen was flagged for independent verification in 2020 as a precaution due to uncertainty in the described range on record; however, the wide high-Arctic range derived from a few collection events indicates this is unlikely to be a species of concern. Laval confirmed the identification under the alternative name *Amphitrite birulai*. *Paramphitrite/Amphitrite birulai* is considered Low Risk and has been placed on the Watch List because it has potentially been flagged as alien in the Adriatic Sea (Costello et al. 2024, Loia 2017) and has an uncertain record in the Canadian Arctic.

In 2023, the specimens were forwarded to Dr. Julio Parapar, a specialist in terebellid polychaetes who originally described *P. tetrabranchiata,* for further review. Dr. Parapar concluded the specimens closely matched the most recent descriptions for *P. birulai*, however, features required for positive identification were missing (Parapar 2023). Additionally, Dr. Parapar noted features on the third segment that are not described for any of the known species in this genus, indicating that these specimens may represent a currently undescribed species, highlighting the requirement for further review of *Paramphitrite*. *P. birulai* will remain on the Watch List pending further review of the genus. Similar to previous years, *P. birulai* was found in low abundances at a range of stations along the eastern and western transects, indicating no meaningful trend in abundance or distribution has been observed in Milne Port since the genus was first recorded in 2020.

- ***Paramphitrite/Amphitrite birulai* is designated Low Risk and will remain on the Watch List.**

8.5.4.3 *Hesperonoe* sp.

Unidentified species from the genus *Hesperonoe* were flagged in benthic infauna samples in 2020 due to a limited range on record. Generally, the genus is considered Arctic-Boreal; however, collections are limited to Arctic waters near Alaska and Russia (GBIF 2024, WoRMS 2024, Degan and Faultwetter 2021).

In 2020, the specimen was sent for independent verification as a precaution due to uncertainty in the taxonomic record and Laval indicated that the specimens could instead be from the genus *Bylgides*, which had been observed previously in the Milne Port baseline and MEEMP surveys (WoRMS 2024, GBIF 2024, Golder 2020). However, Biologica disagreed with the corrected identification, believing the specimens to have visible characteristics that differentiated them from the genus *Bylgides* and were consistent with *Hesperonoe* (MacDonald 2021, pers. comm.). The identification was considered unresolved.

No species of *Hesperonoe* are listed in AIS databases. However, *Hesperonoe* was placed on the Watch List as a Low Risk taxon due to uncertainties in its identification, in the range on record and because it does not have a documented distribution in the Canadian Arctic.

Hesperonoe specimens identified in 2022 surveys were flagged for verification, however, a specialist has not been identified. *Hesperonoe* was identified in samples again in 2023, and these will be sent for verification along with 2022 specimens when an expert is identified. Results of independent review will be presented when available.

- ***Hesperonoe* sp. was designated Low Risk and was placed on the Watch List in 2020, the status remains unchanged pending independent verification.**

8.5.4.4 Bryophyta indet.

An unidentified bryophyte specimen was collected from quadrats located at the mouth of Phillips Creek in 2022. Bryophytes are generally terrestrial and freshwater organisms, and Biologica was unable to definitively identify the species. The bryophyte specimen was set aside to be sent for independent review by a specialist. Results of the independent review remain pending.

There are hundreds of potential species of bryophyte with well-documented natural ranges that include the Eastern Canadian Arctic, including records from terrestrial locations within the region near Ragged Island and Milne Port. Therefore, Bryophyta indet. is tentatively considered to not be a taxon of concern, pending independent review.

- **Bryophyta indet. is designated No Risk and is not considered a taxon of concern in Milne Port.**

8.5.4.5 *Crassicorophium* sp./*Monocorophium* sp.

An amphipod crustacean was identified in 2013 and 2017 samples as *Monocorophium insidiosum* (2013 specimens were identified as *Corophium insidiosum* but corrected to *M. insidiosum* in 2017; Golder 2018). In 2018, individuals from the same genus were found with their identifying features missing and therefore only identified to the genus level. No species within this genus have confirmed distributions that include Arctic waters. *M. insidiosum* is a tube-building gammarid amphipod and a well-known fouling invasive species with a wide global distribution that is possibly non-indigenous to the Canadian Arctic (Molnar et al. 2008). Vectors for introduction

and spread are through biofouling of ship hulls and hard substrates in harbours and ports and possibly also through accidental transplant (Fofonoff et al. 2018, Molnar et al. 2008).

Independent review by Laval of *Monocorophium* specimens suggested that the specimens identified in Milne Port may have been *Crassicorophium bonellii* or *Crassicorophium* sp., although the identification was considered uncertain by Biologica (MacDonald 2020, pers. comm.). This genus naturally occurs in the Canadian Arctic and was first identified in baseline surveys (*C. bonellii,* as *Corophium bonellii*) at Milne Port. *C. bonellii* has a known range similar to *M. insidiosum*, covering Eastern North America and the Northeastern Atlantic Ocean, but is not considered invasive in these locations (GBIF 2024, ETI 2021, Sirenko et al. 2024). The genus *Crassicorophium* contains at least two species (*C. clarencense* and *C. crassicorne*) with a native range that includes Arctic Canada (GBIF 2024, WoRMS 2024).

In 2021, specimens tentatively identified as *Crassicorophium bonellii* were collected for molecular analysis. Results were inconclusive, but indicated the specimens were not *Monocorophium* species or *Crassicorophium bonellii*. The closest match was to unidentified specimens collected from Victoria Island in Nunavut, which were thought to be *C. clarencense* (MacDonald 2022b, pers. comm.). Specimens were also sent to Dr. Craig Straude at Friday Harbor Laboratories at the University of Washington for morphological assessment. Dr. Straude confirmed the identification for *C. clarencense* for specimens analysed based on several validating features (MacDonald 2022c, pers. comm.).

Crassicorophium sp. and *C. clarencense* were observed in Milne Port in 2023.

- ***Crassicorophium* sp. is designated Low Risk and will remain on the Watch List**
- ***Crassicorophium clarencense* is designated No Risk and is not considered a taxon of concern in Milne Port**

8.5.4.6 Marenzelleria sp.

Four specimens of *Marenzelleria* sp. were identified in benthic samples in 2023. *Marenzelleria* is a spionid polychaete genus with a representative species (i.e., *M. viridis*) on the Watch List. *Marenzelleria* sp. were first recorded in Milne Port in 2016 but were not flagged for review until the tentative identification of *M. viridis* in 2018. Specimens from 2018 through 2021 were subsequently corrected to the Arctic species *M. wireni* and potentially *M. arctia* and *M. neglecta* by a specialist in the taxonomic group, with the identification of *M. wireni* further confirmed through DNA analysis. The correction was further supported by environmental conditions at Milne Port matching habitat preferences for *M. wireni, M. neglecta*, and *M. arctia.*

Benthic sampling stations are focussed on repetitive sampling in the same locations to detect changes in abundances or diversity at specific locations. In years where a limited sampling program occurs, station selection includes specific stations targeted where Watch List taxa have previously been observed. Three *Marenzelleria* specimens were collected at two target stations near Phillips Creek where *M. arctia* had previously been detected. While no specimens were collected at target locations surrounding the Ore Dock, one specimen was collected nearby at a new Capesize Station. Since its first detection in 2016, *Marenzelleria* remains difficult to resample, with sporadic collections in low abundances despite targeted sampling, reinforcing the observation that invasive behaviour is not apparent in *Marenzelleria* in Milne Port. No meaningful trend in abundance or distribution has been observed in Milne Port since the genus was first recorded in 2016.

Marenzelleria has an established presence in the Eastern Canadian Arctic, prior to project operations. *Marenzelleria wireni* has been documented at Philpots Island, Lancaster Sound and Scott Inlet, Baffin Island in 1978 (Thomson 1982; Thomson and Cross 1980) in samples that were verified by a polychaete expert at the Canadian Museum of Nature. More recently, a DFO report appears to indicate the genus was detected by genetic means in Lancaster Sound in 2017 and in Hudson Bay in 2016, although supporting information on these detections is not provided by the authors (Morrison et al. 2023). *Marenzelleria* (as *M. viridis*) was also detected in Churchill using metabarcoding in 2011 (Chain et al. 2016), as well as morphology-based identifications in Gjoa Haven (Brown et al. 2011) and in Davis Strait (reported as *Scolelepides viridis* and later updated to *M. viridis,* Stewart et al. 1985).

In the Western Canadian Arctic, *M. arctia* has been found in DFO surveys of Tuktoyaktuk Harbour and Mason Bay, NT in 1980, 1982, 1985, and 1986 (Hopky et al., 1992; Canadian Museum of Nature collections). Specimens from the 1982 surveys were also documented as *Marenzelleria* cf. *viridis*, with the 'c.f.' designation indicating uncertainty that this was the correct nomenclature at the species level (ZSRO 2024). The type specimen of *M. arctia* (as *Scolecolepides arctius*) was collected in Collinson Point, Alaska (approximately 170 km west of the Canadian border), by the Canadian Arctic Expedition in 1913 (Chamberlin, 1920). The California Academy of Sciences collection contains *M. arctia* and *M. wireni* specimens from multiple sites along the Alaska coast of the Beaufort Sea collected in the 1970s and for which the species identity was verified to modern taxonomic descriptions in 2015.

The genus *Marenzelleria* appears from these historical records to have been widely established in the Canadian Arctic, including the Eastern Canadian Arctic, well before the commencement of Baffinland's operations, and the evidence points to at least some members of the genus (*M. arctia, M. wireni*) being native to the region. The status of *M. viridis* in the Canadian Arctic is less clear, as its native range is evidently the Atlantic coast of North America. However, there is a strong possibility it has been misidentified in a number of instances. Identification to the genus level is more certain than identification to species for polychaetes in the genus *Marenzelleria.* Taxonomic keys published for the northeastern coast of North America, and commonly used for identification of Arctic species in the absence of keys to Arctic species, identify all members of *Marenzelleria* genus as the species *M. viridis*. Thus, there is a risk that morphological identifications of *M. viridis* represent potentially misidentified specimens of *M. wireni* or *M. arctia*. *Marenzelleria* sp. can be difficult to distinguish based simply on morphology due to a combination of limited descriptions, overlapping morphological traits, lack of differentiating features in immature specimens, and hybridization between species (Sikorski and Bick 2004; Bick 2005; Blank et al. 2008). *M. viridis*, *M. neglecta*, and *M. arctia* in particular are morphologically similar, resulting in the three species being part of a cryptic sibling species complex (Sikorski and Bick 2004, Bick 2005, Green 2015). The redescriptions of the genus, descriptions of new species based on historical collections (*M. bastropi* and *M. neglecta*), incorrect species nomenclature used in reporting, and synonymization of the former description of *M. jonesi* with *M. viridis* lead to uncertainty in the historical specimen records, particularly where distributions overlap (Blank et al. 2008, Sikorski and Bick 2004). As many historically collected specimens are no longer available, there is an inherent uncertainty as to which species may be represented by these original collections.

Marenzelleria species are known successful invaders to European waters, mediated by ballast water, and thus this genus is listed in AIS databases. Accordingly, this genus is designated as High Risk. However, biogeographic evidence suggests multiple species are indigenous to the Canadian Arctic or may be cryptogenic, while ecological evidence indicates the genus is not showing invasive behaviour in Milne Port. Further, documented occurrences of the genus in waters around Baffin Island prior to the commencement of shipping operations confirm this is not a Project-related introduction (if it is to be considered an introduction at all). For these reasons*, Marenzelleria wireni*

and *Marenzelleria arctia* are designated No Risk and will not be placed on the Program Watch List, however, other members of the genus *Marenzelleria*, and *M. viridis* in particular, will remain on the Watch List where it is subject to heightened monitoring efforts, as a precaution.

- ***Marenzelleria wireni* and *Marenzelleria arctia* are designated No Risk and are not considered taxa of concern in Milne Port.**

8.5.4.7 cf. *Punctaria latifolia*

In 2022, specimens tentatively classified as cf. *Punctaria latifolia* were identified on settlement substrates. While the specimens were an inexact match to the species, *P. latifolia* is a species of bladed brown algae with a broad global range that includes records from the North Atlantic and Greenland Sea (WoRMS 2024, GBIF 2024, AlgaeBase 2023). No records of this species exist in the Canadian Arctic, and it is present on at least one AIS database as cryptogenic in Australia. Due to the limitations in algal taxonomy and Canadian Arctic surveys described in Section 8.3.3.3.2, there is uncertainty in whether this species can be considered alien to the Canadian Arctic, however, the specimens were flagged for further review as a precaution.

As the specimens were not an exact match to *P. latifolia*, it may be that these specimens are of a morphologically related species that is not yet described. Notably, DNA barcoding of algae collected in Churchill identified the presence of a *Punctaria* species that was not able to be matched to any currently described species, resulting in the authors suggesting that it may be a new species (Saunders and McDevit 2013).

- ***Punctaria latifolia* is designated Low Risk and has been placed on the Watch List.**

8.5.4.8 cf. *Stictyosiphon soriferus*

In 2022, cf. *Stictyosiphon soriferus* was tentatively identified on the settlement substrates. While the specimens were an inexact match to the species, *Stictyosiphon soriferus* is a species of brown algae with a broad range on record throughout the North Atlantic and Greenland Sea (WoRMS 2024, GBIF 2024, AlgaeBase 2023). However, although there is a single record of occurrence record in the surrounding region (Churchill), no records exist for this species in the Eastern Canadian Arctic (Saunders and McDevit 2013). Additionally, this species has been recorded as introduced to Australia, likely through the vector of hull fouling (Hewitt et al. 2004).

As the specimens were not an exact match to *S. soriferus*, it may be that these specimens are of a morphologically related species that is not yet described. Due to the limitations in algal taxonomy and Canadian Arctic surveys described in Section 8.3.3.3.2, there is uncertainty in whether this species can be considered alien to the Canadian Arctic, however, the specimens were flagged for further review as a precaution.

- ***Stictyosiphon soriferus* is designated Low Risk and has been placed on the Watch List.**

8.6 Conclusions and Recommendations

The NIS/AIS program addresses Project Terms and Conditions Nos. 87, 89, and 91. Detection is conducted at a surveillance level and designed to flag potential invasive or non-indigenous species introduced through Project-related vectors. Approximately 1,062 taxa (including 410 identifiable to species) have been observed in Milne Inlet through monitoring surveys to date. The vast majority of these taxa have been designated as “No Risk” and are not considered to be of concern. Taxonomic sampling at Milne Port remains one of the most comprehensive multi-trophic level species inventory programs in the Canadian Arctic, a region historically under-sampled in comparison to Eurasian Arctic and Sub-Arctic regions.

Directed literature review of newly observed taxa in 2023 has resulted in no taxa being added to the Project Watch List for increased monitoring effort, such as review by specialists or DNA analysis, and the removal of one taxon (*Sosane wireni*) from the Watch List. However, identification for macroalgal, DNA analysis results, and independent taxonomic verifications for 2023 specimens remain pending.

The complete program Watch List, consisting of eight taxa, is presented in Appendix 8E-3. As yet, there has not been confirmation of Project-related introduction of an NIS/AIS species documented at Milne Port and no species have been placed on the Trigger List to initiate rapid response. Based on the number of specimens flagged and sent for independent verification, monitoring is considered to be effective and is functioning as intended.

The following are recommendations for the ongoing NIA/AIS program:

- **Continue sampling across multiple trophic levels (including zooplankton sampling as conducted in 2023) in 2024.**
- **Continue expanding the Milne Inlet Taxonomic Inventory.**
- **Continue screening flagged specimens for known geographic ranges and NIS/AIS status.**
- **Continue collecting and reviewing genetic evidence for *Marenzelleria* sp. and *Monocorophium* sp., in addition to macroflora, bryozoan, and tunicate taxa in general, including targeted sampling to obtain specimens for DNA barcoding to further resolve these taxonomic groups in Milne Port.**

8.7 Closure

We trust this information is sufficient for your needs at this time. Should you have any questions or concerns, please do not hesitate to contact Phil Rouget, on behalf of the undersigned, at +1 250 419 4945.

APPENDIX 8A-3

Benthic Infauna Laboratory Methods

Marine Benthic Enumeration and Identification Methods
Client: WSP
Project: Baffinland MEEMP
Protocol: EEM

Sample Inventory

Sample arrival: 7-Sep-23
Number of samples: 44
Number of jars: 67
Screen size: 500 µm and 1.0 cm
Biologica project number: mb23-059

The chain of custody documents were checked and approved with the client. Samples were transferred from formalin into 70% ethanol and stained with Rose Bengal to aid in sorting. Each sample was provided a unique identification number and placed in the queue for analysis.

Table 1. Summary of benthic samples processed for WSP Baffinland MEEMP, 2023.

Sample Processing

Sorting and Subsampling:

All samples were sorted using dissecting microscopes at 10–40x magnification by trained personnel. Microscopic sorting is the only way to ensure >90% of organisms are removed from the debris, which is required by EEM (Environment Canada; Environmental Effects Monitoring) guidelines for marine benthic analyses. To minimize potential sorter bias, samples were distributed among technicians such that no one person sorted all the replicates of a given sample.

Due to historically the large volumes and high abundances in the samples, samples were fractioned in the field into a 1.0 cm macro fraction and 500 µm fine fraction. This strategy was developed to maximize the detection of large and rare individuals in the macro fraction while accurately enumerating smaller organisms in the fine fraction. The macro 1.0 cm fraction was analyzed whole, with all large organisms (>1.0 cm) removed from the sample, as was done in previous years for this project. In addition, all large debris in this fraction were checked microscopically, including rocks and other large debris to ensure encrusting organisms were accurately enumerated.

Biologica subsampled the fine 500 µm fraction. The 500 µm fraction was split in the field to 1/4. Biologica subsequently split this fraction by a second 1/4 split, for a final 1/16 split. Subsampling was done with a Caton tray (Caton, 1991). The sample was spread evenly over a Caton grid, and

sequential random quadrats were selected and sorted until the minimum 1/4 lab split was reached.

Sub-sampling accuracy was assessed by sorting the remaining sample for 10% (n= 4) of all sub-sampled samples and comparing the fractions to one another. Refer to Table 2 for sub-sampling accuracy results.

Sorting QA/QC:
To ensure sorting efficiency was >95%, whole and/or partial sub-samples were re-sorted. Sorting efficiency was calculated using the following equation (where total count = final total number of organisms in sample):

Sorting efficiency = [1−(# of organisms in spot check or re-sort / total organisms)] x 100
*Total organisms includes the original count and the number found from the re-sort

All samples checked must meet or exceed 95% sorting efficiency. Any samples falling below 95% sorting efficiency are re-sorted in their entirety, and additional checks are undertaken as necessary. For quality assurance, QA re-sorts were performed on 10% of samples. Four samples were randomly selected and re-sorted in their entirety. Refer to Table 2 for sorting efficiency results.

Table 2. Summary of sorting QA/QC results for WSP Baffinland MEEMP, 2023.

Client Sample ID	Biologica Sample ID	Sorting Efficiency QA Whole Re-sorts	Sub-sampling accuracy
SCV-2	mb23-059-114	99.05%	
SE-4	mb23-059-118		74.21%
SNE-1	mb23-059-125	95.37%	
SNW-1	mb23-059-135		66.88%
SW-3	mb23-059-147	96.43%	
SW-4	mb23-059-148		76.36%
SW-12	mb23-059-154	97.99%	
SW-15	mb23-059-156		77.98%
	Average:	**97.12%**	**73.86%**

Identification and Invasive Species Detection:

All organisms were identified using a combination of dissecting (10–40x) and compound microscopes (100–1000x) and standard taxonomic keys (see methodological and taxonomic references) to the lowest practicable level (species whenever possible). All specimens were archived in air-tight glass vials with glycerin and 70% ethanol for long-term storage. Taxonomic data were recorded in Biologica's custom database.

During the identification process, taxonomists recorded if any identified taxa were beyond their recorded range and/or potentially introduced (originating from another location) or invasive (both introduced and appearing to proliferate with possible detrimental effects to the ecosystem and/or industry). One genus of interest over the past several years of sampling has been *Marenzelleria.* Multiple specimens were externally verified by DNA analysis by Dr. Vasily

Radashevsky from the National Scientific Center of Marine Biology and were confirmed to be *Marenzelleria wireni*. Historical identifications can all be taken to this species identification. **No taxa observed were identified as putative invasive taxa**.

Twelve new taxa to the project were identified, of which will be sent for verification. There were also a few levels of identification that were new to the project, however all these identifications have been present at a lower level (genus/species) in the past.

Reference Collection:

Biologica houses a reference collection of all taxa that have been observed in the Baffinland MEEMP project thus far. Taxa are added to this reference collection yearly. These may be new taxa and/or new stages. Taxa new to the project are sent for external verification. This collection consists of a minimum of one specimen representing each taxon and stage, with five specimens per taxon/stage wherever possible. These specimens were labelled, given a location code, and placed in evaporation-resistant shell dram vials. Approximately 1 mL of glycerin was added to each vial to prevent desiccation.

Data Management and Analysis

All data were recorded in Biologica's custom database. Total abundances were extrapolated for samples split in the field and the lab to represent the abundance from the whole sample. Organism densities were calculated by dividing the total organism abundance (extrapolated if the sample was split) using the area of a Van Veen grab (0.1 m^2), with three composite Van Veen grabs (3 x 0.1m^2) for each sample.

Results were provided to the WSP project manager in Excel spreadsheets via email.

		# Unique Taxa each year	**69**	**110**	**61**
		TOTAL # Taxa (COUNT)	**97**	**158**	**81**

Notes: taxa identified to the lowest practical taxonomic level; indet.= indeterminate (taxa which could not be identified beyond the taxonomic level listed); sp.=species; cf.=compare with (taxa is an inexact match to the designated taxa). X indicated unique taxa in sample year, Y indicates taxon was observed, but lower taxonomic levels were observed the same year.
Taxa in bold indicate new observations in MEEMP and NIS/AIS programs
All taxa cross-referenced with NIS/AIS resources: Fofonoff et al. 2023, ISSG 2023, Rius et al. 2023, AquaNIS 2023, Molnar et al. 2008, Casas-Monroy et al. 2014

APPENDIX 8C-2

Settlement Substrate Laboratory Data 2023

biologica

Abundance data in long format for WSP Baffinland MEEMP, 2023 Freight Dock Settlement Subtrates including both plates and baskets.

						Total Taxa Observed	**49**	**33**	**59**	**61**	**41**	**46**	**49**	**70**

Notes: Taxa in bold indicate the first observation of the taxa during MEEMP and NIS/AIS surveys. Taxa identified to the lowest practical taxonomic level; presence/absence for previous years taken from SEM 2015, 2016, 2017a, Golder 2018, Golder 2019a, Golder 2020a, Golder 2021a, WSP 2023. *=Species or taxa from lower taxonomic levels identified in other survey years and/or in other survey methods; **=Freshwater taxon; ***= Incidental (benthic or terrestrial taxa or life stages); indet.= indeterminate (taxa could not be identified beyond the taxonomic level listed); sp.=species.
(a) Baseline includes zooplankton observations in 2008, 2010, 2014, and 2015.

APPENDIX 8D-3

Zooplankton Laboratory Methods

Marine Zooplankton Enumeration and Identification Methods
Client: WSP
Project: Baffinland MEEMP

Sample Inventory

Sample arrival: 7-Sep-23, 19-Sep-23
Number of samples: 24, 12
Number of jars: 24, 12
Field screen size: Horizontal Tows = 250 µm
Vertical Tows = 64 µm
Biologica project number: mz23-059

Upon arrival, the samples were examined and double-checked against the chain of custody to ensure that (1) all samples were accounted for, and (2) each sample had the appropriate number of jars as indicated on the COC. Any discrepancies were reported to the client and were resolved before further sample handling. Samples were assigned a unique internal identification number and stored in ascending order in the sample storage area. For processing, samples were analyzed in water and then transferred into 10% Formalin for storage.

Sample Processing

Marine zooplankton samples were analyzed in 2-4 fractions as described below. All subsamples are obtained using a Folsom Splitter. Among the subsamples, a total count of a minimum of 300 organisms were identified.

(1) A "URL" fraction (Unique, Large, and Rare) comprised of unique, large and rare organisms. These tend to have low abundance. The whole sample is scanned and these organisms are removed for identification. Ichthyoplankton are included in this fraction unless they have very high abundances.
(2) One to four fraction(s) comprised of all remaining organisms in the sample. The number of fractions is determined by the size distribution and abundances of organisms in the sample. Counts are included in the fraction which most accurately captures the per-taxon abundances. All taxa (and stages/size class) are identified in only one fraction per sample. Fractions are assigned with the smallest split listed as "Fraction 1" and largest split is listed as the last fraction.

The fractions were analyzed through a stereo microscope at 10–40x magnification. All organisms were identified by taxonomic experts to the lowest taxonomic level using a compound microscope (100–400x magnification), appropriate dissection tools, and standard taxonomic references. For copepods, the stage of development was also recorded (copepodite stages I–V) as is the sex for mature individuals (copepod stage VI).

In addition, all taxa, including copepods, were assigned a size class consistent with sizing of the Zooplankton Taxonomy Laboratory at the Institute of Ocean Sciences (Sidney, BC). These size stages are explained in Table 1.

Table 1. Definition of size class stages

Size Class Code	Size (mm)
S0	< 1.0
S1	1.0 - < 5.0
S2	5.0 - < 10.0
S3	10.0 - < 15.0
S4	15.0 - < 20.0
S5	20.0 - < 25.0
S6	25.0 - < 30.0
S7	30.0 - < 35.0
S8	35.0 - < 40.0
S9	40.0 - < 45.0
S10	45.0 - < 50.0

Zooplankton were identified to species wherever possible, although immature copepods lack differentiating features required for identification beyond order (e.g., Calanoida, Cyclopoida, or Harpacticoida). All identifications were performed using taxonomic references and collaborations with external experts, where necessary.

Table 2. Summary of zooplankton samples processed for WSP Baffinland MEEMP, 2023.

*Freshwater taxa, eggs and MEMO organisms not included in raw specimen count.

QA/QC

Ten percent (n=3) of samples were reanalyzed to assess subsampling accuracy and consistency of enumeration. The sample was chosen at random and processed at different times to reduce counting and identification bias. The results of this assessment are reported in Table 3.

Table 3. Summary of taxonomic QA/QC results for WSP Baffinland MEEMP, 2023.

Biologica Sample ID	Client Sample ID	Total Abundance (Original Replicate)	Total Abundance (QA Replicate)	Percent Agreement
mz23-059-168	ZH-03	5,773	5,445	94.32
mz23-059-187	ZV-06	15,349	17,285	87.39
mz23-059-241	ZH-02	12,696	10,793	85.01
			Average	**88.91**

Percent Agreement:
{100 – [(difference in abundance between samples/total abundance of original sample) x 100]} %

Data

Taxonomic data were recorded in Biologica's custom database. Results were provided to the WSP project manager in Excel spreadsheets via email.

All taxa cross-referenced with NIS/AIS resources: Fofonoff et al. 2022, ISSG 2022, Rius et al. 2022, Molnar et al. 2008, Casas-Monroy et al. 2014.

**Marenzelleria* sp. are on the Watchlist, however specimens were damaged, lacking features required to resolve identification with confidence and were therefore not sent for verification. The specimens closely matched *M. wireni*, but the identification could not be confirmed.

Note: Grey cells indicate no action (i.e., no specimen in samples, therefore none sent for verification)
* Biologica: Biologica Environmental Services; Laval: The Benthic Ecology Lab at Université Laval; CCDB: Canadian Centre for DNA Barcoding at the University of Guelph, Radashevsky: Dr. Vasily Radashevsky of the Russian National Scientific Center of Marine Biology; Parapar: Dr. Julio Parapar, Departamento de Bioloxia, Universidade da Coruna; Friday Harbor: Dr. Craig Staude at Friday Harbour Laboratories at the University of Washington
**EcoAnalysts and Columbia Science examined specimens from 2018 and 2019 collections
*** Radashevsky examined specimens from 2017-2020, no specimens matched *M. viridis*, at least one specimen was conclusively identified as *M. wireni*, a high probability of *M. arctia* was given for specimens from Phillips Creek, other specimens were a high probability of *M. wireni* and/or *M. neglecta*
**** Dr. Parapar concluded that specimens matched the most up to date descriptions for *Ampharete petersenae* and *Paramphitrite birulai*, however the identification was not positive based on missing features and limited taxonomic data for both genera

APPENDIX 8E-3

Program Watch List

Program Watch List

Phylum Class/Order	Family	Subfamily	Taxa	Risk Category	Year Added	Year Removed
Annelida						
Polychaeta/Phyllodocida	Polynoidae	Polynoinae	*Hesperonoe* sp.	Low Risk	2020	N/A
Polychaeta/Sabellida	Fabriciidae	-	*Pseudofabricia* sp. nr. *aberrans*	No Risk	2018	2021
Polychaeta/Spionida	Spionidae	-	*Marenzelleria viridis* (*Marenzelleria* sp.)*	High Risk	2019	N/A
Polychaeta/Terebellida	Ampharetidae	Ampharetinae	*Ampharete petersenae*	No Risk	2020	2021
Polychaeta/Terebellida	Ampharetidae	Ampharetinae	*Sosane wireni*	No Risk	2019	2023
Polychaeta/Terebellida	Terebellidae	-	*Amphitrite birulai/Paramphitrite birulai****	Low Risk	2020	N/A
Arthropoda						
Malacostraca/Amphipoda	Corophiidae	Corophiinae	*Crassicorophium* sp.	Low Risk	2018**	N/A
Malacostraca/Amphipoda	Corophiidae	Corophiinae	*Monocorophium* sp.	High Risk	2018**	N/A
Chordata						
Actinopterygii/Perciformes	Ammodytidae	-	*Ammodytes hexapterus*	Low Risk	2020	N/A
Ochrophyta						
Phaeophyceae/Ectocarpales	Chordariaceae	-	*Punctaria latifolia*	Low Risk	2022	N/A
Phaeophyceae/Ectocarpales	Chordariaceae	-	*Stictyosiphon soriferus*	Low Risk	2022	N/A

**Marenzelleria viridis* and *Marenzelleria* species, other than *M. wireni* and *M. arctia*

** *Monocorophium* and *Crassicorophium* sp. were previously identified during baseline surveys, but flagged for review in 2018

*** Specimens examined by Dr. Julio Parapar were determined to match the description of *Paramphitrite birulai*, however there is uncertainty in the taxonomic description that indicate that these specimens may be from a related, undescribed genus
